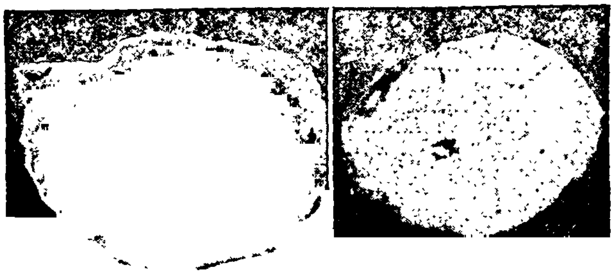
Unhemolyzed blood is placed in a chemically clean centrifuge tube and centrifuged for 2 to 10 minutes to produce cell-free serum or plasma. Two samples are drawn into an ordinary hemoglobin pipet to the 0.02 cc. mark and transferred to the two depressions of one of the slides; 0.02 cc. aliquots of the 3 and 5 mm. per liter standard potassium solutions are placed in the depressions of the second slide. The same pipet may be used for all four deliveries. Then 0.01 cc. of the sodium cobaltinitrite reagent are added with a suitably marked hemoglobin pipet to each of the specimens in the following order: first, to an unknown, then to the 3 and 5 mm. standard solutions, and finally to the duplicate unknown. Time is eliminated as a factor in the speed of occurrence of the precipitate in the unknowns as compared to the standard solutions when the cobaltinitrite reagent is added in this order. Each sample is then thoroughly mixed for five seconds with the rubber-tipped stirring rod, with a rapid circular motion, the rod being wiped dry between stirrings. Rapid complete mixing of the solutions is essential to insure an even distribution of the precipitate and requires practice. The test slide is then placed on a glossy black film, and the intensity of the precipitate formed by the standard solutions is compared with the unknowns. The precipitate is best seen when light is directed across the slide. The 5 mm. per liter standard potassium solution develops a diffuse, whitish yellow, cloudy precipitate within 10 seconds, but the 3 mm. per liter standard remains clear for about 20 seconds, and then slowly develops a faint white precipitate around the periphery (see figure). The time of occurrence and degree of potassium precipitation depends on temperature [1]; at low temperatures the potassium sodium cobaltinitrite precipitate occurs sooner and is more pronounced than it is at higher temperatures. If the temperature is above 80 F (27 C) and a clear distinction between the 3 and 5 mm. solutions cannot be made, cooling the unknown and standards will render the precipitate more readily visible. The temperature of the standards and the unknowns must be the same. The reading can often be completed within 30 seconds and must be made within about 5 minutes. The unknowns are classified as follows: 1, if they contain less precipitate than the 3 mm. per liter potassium standard; 2, if they contain about the same amount of precipitate as the 3 mm. per liter standard; 3, if they contain an amount of precipitate intermediate between the 3 and 5 mm. per liter potassium standards; 4, if they contain about the same amount of precipitate as the 5 mm. per liter potassium standard; and 5, if they contain a greater amount of precipitate than the 5 mm. per liter potassium standard.



Comparison of precipitates formed with 3 mm. per liter potassium standard solution (left) and 5 mm. per liter standard solution (right) when the sodium cobaltinitrite reagent is added.

When unknowns contain more than 5 mm. of potassium per liter, the potassium concentration can be approximated by diluting the unknown with an equal part of water or isotonic sodium chloride solution and using 0.02 cc. of the diluted specimen for the test. A

From the Laboratory of Kidney and Electrolyte Metabolism, National Heart Institute, National Institutes of Health, Bethesda, Md., and the Children's Medical Service, Massachusetts General Hospital, and Department of Pediatrics, Harvard Medical School, Boston.

[1] Burgess, L. L., and Kamm, O.: A Study of Cobaltinitrites and Their Application to Analytical Chemistry, J. Am. Chem. Soc. 34: 652, 1912.

sample containing 10 mm. per liter of potassium, so diluted, will give a precipitate equal to the 5 mm. standard, and one containing 6 mm. per liter of potassium will give a precipitate equal to the 3 mm. per liter standard.

PRECAUTIONS

The following precautions should be observed: 1. The test slide should be kept scrupulously clean and free of abrasions so that the fine potassium-sodium cobaltinitrite precipitate is evenly distributed and can be clearly identified. 2. It is inadvisable to read the unknown if either it or the standards contain a localized precipitation of the cobaltinitrite salt. 3. Both standard potassium solutions should be run each time a test is done; if a distinct difference is not present, either a fresh lot of the cobaltinitrite reagent should be made, or the standards checked. We have kept a 15% solution of sodium cobaltinitrite in the ice box for six months and found it to be satisfactory. 4. Cigarette ash may interfere with the accuracy of the test. There are about 2.2 mcg. of potassium in 0.02 cc. of the 3 mm. standard solution; thus, even a trace of high potassium containing ash may interfere with the reading. 5. Contamination of serum with red or white cells will give a falsely high value. 6. Grossly lipemic serum cannot be used unless it is cleared. Ethyl ether, chemically pure, 4 parts, and serum, 1 part, are shaken vigorously in a test tube for one minute and then centrifuged. The supernatant ether and fatty plasma layer are removed and the remaining plasma is used for the potassium determination.[2]

Comparison of Potassium Concentrations Obtained by Photometric and Turbidometric Methods*

Determinations on Whole Serum

Group †	Turbidometric K Concentration, mEq. per Liter	Photometric Concentration, mEq. per Liter: 2-2.9	3-3.9	4-4.9	5-5.9	Over 6.0
5	More than 5	..	..	..	..	37
4	5	..	..	15	4	..
3	Between 3 and 5	..	27	44	1	..
2	3	2	11	..	..	..
1	Less than 3	4	..	..	..	..

Determinations on Diluted Serum

Group	Turbidometric K Concentration mEq. per Liter	Photometric Concentration, mEq. per Liter: Less than 6	6-6.9	7-7.9	8-8.9	9-9.9	10-10.9
5	More than 10	..	..	..	..	..	1
4	10	..	..	..	..	2	4
3	Between 6 and 10	..	1	3	3	4	3
2	6	..	3	6	3	..	..
1	Less than 6	..	2	2	..	..	..

* The numbers in the body of the table represent the number of determinations.

† See the text for an explanation of the classification.

RESULTS

A total of 145 serum samples with potassium concentrations ranging from 2 to 10 mm. per liter, as determined by a Barclay flame photometer with an internal lithium standard,[3] were reanalyzed for their potassium content by the method described above. The results of these determinations, listed in the table, show agreement adequate for most clinical purposes. Serums read as groups 1 and 5 by the slide method always contained abnormal concentrations of potassium as determined by the flame photometer.

COMMENT

The specificity of sodium cobaltinitrite for the precipitation of potassium has been reviewed by Peters and Van Slyke.[4] Silver, mercury, cesium, thallium, rubidium, and ammonia also form insoluble cobaltinitrites, but these substances are not present in sufficient quantities in fresh blood to interfere with this test.[5] Ammonia and organic acids interfere with the analysis of urine potassium by this method.[1] Stored plasma may contain large amounts of ammonia, due to the breakdown of proteins, amino acids or urea, and unless it is specially prepared, is unsuitable for analysis by this method.[4]

The micro potassium method described herein is readily applicable to clinical use. Thus the physician without access to special laboratory equipment or trained laboratory personnel no longer need be in doubt during parenteral fluid therapy that hypokalemia or hyperkalemia is present.

SUMMARY

A micromodification of the cobaltinitrite method for the determination of serum potassium content is described. With the use of equipment available in the simplest laboratory, the serum potassium concentration can be estimated in a few minutes.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT OF THE COUNCIL

The Council has authorized publication of the following report.

R. T. STORMONT, M.D., *Secretary.*

USE OF MUSCLE RELAXANTS

When the skeletal muscle relaxing drugs were first introduced, it was both hoped and expected that their use would permit a lowering of the operative mortality rate by permitting the surgeon to do effective work at a lower level of anesthesia or more effective work at the usual levels. There is no doubt that surgeons find certain kinds of operations can be more easily performed after the skeletal muscles have been relaxed by a drug of this group and that the total dose of anesthetic sometimes can be diminished by this means. Increasing evidence indicates, however, that these undoubted advantages have been attained at a price of occasional untoward effects and sometimes of serious difficulty.

That the skeletal muscle relaxants may cause failure of respiration is well known. The margin of safety between the dose necessary to produce good relaxation of voluntary muscles and that which paralyzes respiration is unfortunately small; but if failure of respiration is promptly detected and energetically treated by artificial respiration and oxygen, rapid recovery should be effected, with no untoward after-effects. Clearly, facilities for satisfactory respiration must always be on hand when muscle relaxants are to be used.

Much more serious is the circulatory collapse, easily demonstrated in animal experiments after overdosage of these drugs, and occasionally seen in patients after use of these agents, even though the dosage does not exceed that usually well tolerated. This collapse does not always respond to such measures as intravenous injections of blood, blood substitutes, or vasoconstrictor drugs. Antidotes such as neostigmine and physostigmine are often of little or no assistance. In fact, after administration of succinylcholine, they are contraindicated.

Toxic manifestations suggesting involvement of the central nervous system, effects that may again be demonstrated in animal preparations after overdosage, also are seen occasionally in patients after proper doses of these drugs. These serious forms of toxicity may be difficult or impossible to handle satisfactorily.

The operative mortality rate in good hospitals is now so low that surgeons and anesthetists may not encounter a death for long periods. It is also true that many anesthetists have used muscle relaxants without meeting with serious difficulties. However, it is not yet clear whether this is merely a fortunate coincidence, for the Council has been informed that certain unpublished data indicate a significantly higher operative mortality when these drugs are used. In any case it should be more generally realized that muscle relaxants are potent agents and as such are not devoid of danger. They should not be used routinely or indiscriminately and should be employed only when an important advantage can be gained for the patient.

The following abstract of recent nomenclature decisions of the Council is authorized for publication.

R. T. Stormont, M.D., *Secretary.*

NEW GENERIC AND BRAND NAMES RECOGNIZED BY THE COUNCIL

The Council collaborates with manufacturers in the selection of generic and brand names for marketed drug preparations presented for acceptance and also for new products still under development or clinical trial. The last report on such names appeared in The Journal, June 20, 1953, p. 709.

The following abstract lists the generic designation, the chemical name, where necessary for information, and the brand name or names simultaneously recognized for the stated firms. In general, a generic name should bear recognizable relation to the chemical name and conform as closely as consistent with brevity and practicality to existing systems of scientific nomenclature. The chief requirement for a brand name is that it should not be therapeutically suggestive.

The listing of a brand name is not to be construed as indicating Council acceptance of the product itself. Products accepted for inclusion in New and Nonofficial Remedies are announced separately.

Absorbable Gelatin Film for an absorbable, water-insoluble, non-hemostatic, non-porous, transparent gelatin-base film: Gelfilm (The Upjohn Company)

Alphaprodine Hydrochloride for *dl*-alpha-1,3-dimethyl-4-phenyl-4-propionoxypiperidine hydrochloride: Nisentil Hydrochloride (Hoffmann-LaRoche, Inc.)

Bacitracin-Neomycin for a mixture of bacitracin and neomycin sulfate: Bacimycin (Walker Laboratories, Inc.)

Benoxinate Hydrochoride for 2-diethylaminoethyl 4-amino-3-*n*-butoxybenzoate hydrochloride: Dorsacaine Hydrochloride (Smith-Dorsey, Division of The Wander Company)

Cyclopentylate Hydrochloride for β-dimethylaminoethyl (1-hydroxycyclopentyl)phenylacetate hydrochloride: Cyclogyl Hydrochloride (Schieffelin & Company)

Fructose for D-fructose: Levugen (Mead Johnson & Company)

Furazolidone for N-(5-nitro-2-furfurylidene)-3-amino-2-oxazolidone: Furoxone (Eaton Laboratories, Inc.)

Glycobiarsol to replace Bismuth Glycolylarsanilate: Milibis (Winthrop-Stearns Inc.)

Mepiperphenidol Bromide for 1-(3-hydroxy-5-methyl-4-phenylhexyl)-1-methylpiperidinium bromide: Darstine Bromide (Sharp & Dohme, Division of Merck & Co., Inc.)

Methylergonovine Tartrate for *d*-lysergic acid-(+)-butanolomide-(2) tartrate: Methergine Tartrate (Sandoz Pharmaceuticals)

Piperphenidol Hydrochloride for 5-methyl-4-phenyl-1-(1-piperidyl)-3-hexanol hydrochloride: Reltine Hydrochloride (Sharp & Dohme, Division of Merck & Co., Inc.)

Primidone for 5-phenyl-5-ethylhexahydroprimidine-4,6-dione: Mysoline (Ayerst, McKenna & Harrison, Ltd.)

Vitamin B_{12} with Instrinsic Factor Concentrate for a mixture of crystalline vitamin B_{12} and a partially purified preparation of the intrinsic factor (Castle) derived from hog stomach mucosa: Bifacton (Organon, Inc.)

COUNCIL ON FOODS AND NUTRITION

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council.

James R. Wilson, M.D., *Secretary.*

Dorset Foods, Ltd., Long Island City, New York.

Dorset Brand Diet Pack Condensed Cream of Mushroom Soup.

Ingredients: Fresh mushrooms, whole powdered milk, wheat flour, cornstarch, cottonseed oil, tomato purée, onion powder, spices (no sugar or salt added), and sufficient water for proper preparation.

Analysis (submitted by manufacturer).—Total solids 8.47%, moisture 91.53%, ash (minerals) 0.88%, fat (ether extract) 1.96%, protein (N × 6.25) 1.48%, crude fiber 0.14%, carbohydrate other than crude fiber (by difference) 4.01%, sodium 49 mg./100 gm.

Calories.—0.40 per gram; 11.3 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Dorset Brand Diet Pack Condensed Pea Soup.

Ingredients: Green split peas, wheat flour, carrots, cottonseed oil, onion powder, spices (no sugar or salt added), and sufficient water for proper preparation.

Analysis (submitted by manufacturer).—Total solids 17.75%, moisture 82.25%, ash (minerals) 0.97%, fat (ether extract) 1.09%, protein (N × 6.25) 4.28%, crude fiber 0.36%, carbohydrate other than crude fiber (by difference) 11.05%, sodium 14 mg./100 gm.

Calories.—0.71 per gram; 20.1 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Dorset Brand Diet Pack Condensed Tomato & Rice Soup.

Ingredients: Tomato purée, rice, wheat flour, cottonseed oil, onion powder, lemon juice, celery powder, spices (no sugar or salt added), and sufficient water for proper preparation.

Analysis (submitted by manufacturer).—Total solids 11.83%, moisture 88.17%, ash (minerals) 0.60%, fat (ether extract) 1.39%, protein (N × 6.25) 1.33%, crude fiber 0.34%, carbohydrate other than crude fiber (by difference) 8.17%, sodium 22 mg/100 gm.

Calories—0.51 per gram; 14.5 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Dorset Brand Diet Pack Condensed Vegetable Soup.

Ingredients: Tomato purée, green split peas, wheat flour, carrots, string beans, dehydrated potatoes, turnips, baby lima beans, cottonseed oil, barley, sweet potatoes, macaroni, corn, onion, celery, spices (no sugar or salt added), and sufficient water for proper preparation.

Analysis (submitted by manufacturer).—Total solids 13.53%, moisture 86.47%, ash (minerals) 0.92%, fat (ether extract) 1.19%, protein (N × 6.25) 2.21%, crude fiber 0.54%, carbohydrate other than crude fiber (by difference) 8.67%, sodium 33 mg./100 gm.

Calories.—0.54 per gram; 15.3 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

THE CLINICAL MEETING

AMERICAN MEDICAL ASSOCIATION

St. Louis, December 1-4, 1953

OFFICIAL CALL

TO THE OFFICERS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The clinical meeting of the American Medical Association will be held in St. Louis, Mo., Dec. 1-4, 1953.

The House of Delegates will convene at 10 a. m., Tuesday, Dec. 1, in the Gold Room of the Jefferson Hotel. In the House the representation of the various constituent associations for the clinical meeting in 1953 is as follows:

Alabama	2
Arizona	1
Arkansas	1
California	12
Colorado	2
Connecticut	3
Delaware	1
District of Columbia	2
Florida	2
Georgia	2
Idaho	1
Illinois	10
Indiana	4
Iowa	3
Kansas	2
Kentucky	2
Louisiana	2
Maine	1
Maryland	2
Massachusetts	5
Michigan	6
Minnesota	4
Mississippi	2
Missouri	4
Montana	1
Nebraska	2
Nevada	1
New Hampshire	1
New Jersey	5
New Mexico	1
New York	17
North Carolina	3
North Dakota	1
Ohio	7
Oklahoma	2
Oregon	2
Pennsylvania	11
Rhode Island	1
South Carolina	2
South Dakota	1
Tennessee	3
Texas	6
Utah	1
Vermont	1
Virginia	2
Washington	3
West Virginia	2
Wisconsin	3
Wyoming	1
Alaska	1
Hawaii	1
Isthmian Canal Zone	1
Puerto Rico	1

The scientific sections of the American Medical Association, the Medical Corps of the Army, the Medical Corps of the Navy, the Medical Corps of the Air Force, the Public Health Service and the Veterans Administration are entitled to one delegate each.

The Scientific Program will open Tuesday, Dec. 1, starting at 1:30 p. m., and will continue throughout the afternoon of that day. The program will continue on Wednesday and Thursday mornings and afternoons, Dec. 2 and 3, and on Friday *morning, Dec. 4, closing at 12 noon.*

The Registration Bureau, which will be located in the St. Louis Municipal Auditorium, will be open from 8:30 a. m. until 5:30 p. m., Tuesday, Wednesday and Thursday, Dec. 1-3, and from 8:30 a. m. to 12:00 noon, Friday, Dec. 4.

EDWARD J. MCCORMICK, President.
JAMES R. REULING, Speaker, House of Delegates.
GEORGE F. LULL, Secretary.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION, 1953-1954

PRESIDENT—Edward J. McCormick, Toledo, Ohio.

PRESIDENT-ELECT—Walter B. Martin, Norfolk, Va.

VICE PRESIDENT—Carl H. Gellenthien, Valmora, N. Mex.

SECRETARY AND GENERAL MANAGER—George F. Lull, Chicago.

ASST. SECRETARY—Ernest B. Howard, Chicago.

TREASURER—J. J. Moore, Chicago.

SPEAKER, HOUSE OF DELEGATES—James R. Reuling, Bayside, N. Y.

VICE SPEAKER, HOUSE OF DELEGATES—E. Vincent Askey, Los Angeles.

EDITOR—Austin Smith, Chicago.

BUSINESS MANAGER—Thomas R. Gardiner, Chicago.

BOARD OF TRUSTEES—D. B. Allman, Atlantic City, N. J., 1954; F. J. L. Blasingame, Wharton, Texas, 1954; L. W. Larson, Bismarck, N. D., 1955; T. P. Murdock, Meriden, Conn., 1955; J. P. Price, Florence, S. C., 1956; D. H. Murray, Chairman, Napa, Calif., 1957; James R. McVay, Kansas City, Mo., 1957; E. S. Hamilton, Kankakee, Ill., 1958; G. Gundersen, LaCrosse, Wis., 1958; the President and the President-Elect.

STANDING COMMITTEES OF THE HOUSE OF DELEGATES

JUDICIAL COUNCIL—E. R. Cunniffe, Chairman, New York, 1954; L. A. Buie, Rochester, Minn., 1955; W. F. Donaldson, Pittsburgh, 1956; H. L. Pearson Jr., Miami, Fla., 1957; G. A. Woodhouse, Pleasant Hill, Ohio, 1958; G. F. Lull, Secretary, Chicago.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS—W. L. Pressly, Due West, S. C., 1954; C. T. Stone Sr., Galveston, Texas, 1954; Harvey B. Stone, Baltimore, 1955; J. M. Faulkner, Boston, 1955; Guy A. Caldwell, New Orleans, 1956; John W. Cline, San Francisco, 1956; F. D. Murphy, Lawrence, Kan., 1957; H. G. Weiskotten, Chairman, Skaneateles, N. Y., 1957; Victor Johnson, Rochester, Minn., 1958; L. S. McKittrick, Boston, 1958; Edward L. Turner, Secretary, Chicago.

COUNCIL ON SCIENTIFIC ASSEMBLY—S. P. Reimann, Philadelphia, 1954; A. McMahon, St. Louis, 1954; C. A. Lincke, Carrollton, Ohio, 1955; M. E. DeBakey, Houston, Texas, 1956; S. P. Newman, Denver, 1957; H. R. Viets, Chairman, Boston, 1958; C. H. Phifer, Chicago, 1958; W. B. Martin, Norfolk, Va., ex officio.

COUNCIL ON MEDICAL SERVICE—Joseph D. McCarthy, Omaha, 1954; H. B. Mulholland, Charlottesville, Va., 1955; C. E. Wertz, Buffalo, 1956; Elmer Hess, Chairman, Erie, Pa., 1957; L. M. Orr II, Orlando, Fla., 1958; R. B. Homan Jr., El Paso, Texas, 1958; E. J. McCormick, Toledo, Ohio; Louis H. Bauer, Hempstead, N. Y.; David B. Allman, Atlantic City, N. J.; Mr. Thomas A. Hendricks, Secretary, Chicago.

COUNCIL ON CONSTITUTION AND BYLAWS—F. S. Winslow, Rochester, N. Y., 1954; B. E. Pickett Sr., Carrizo Springs, Texas, 1955; L. A. Buie, Chairman, Rochester, Minn., 1956; J. Stevenson, Tulsa, Okla., 1957; S. H. Osborn, Hartford, Conn., 1958; E. S. Hamilton, Kankakee, Ill.; the President and the Speaker and Vice Speaker of the House of Delegates.

STANDING COMMITTEES OF THE BOARD OF TRUSTEES

COUNCIL ON PHARMACY AND CHEMISTRY—W. C. Cutting, San Francisco, 1953; Keith S. Grimson, Durham, N. C., 1953; Morris Fishbein, Chicago, 1953; M. H. Seevers, Ann Arbor, Mich., 1953; Joseph Stokes Jr., Philadelphia, 1954; Perrin H. Long, Brooklyn, 1954; W. G. Workman, Bethesda, Md., 1954; J. Bordley III, Cooperstown, N. Y., 1954; Carl A. Dragstedt, Chicago, 1955; Isaac Starr, Philadelphia, 1955; Joseph Hayman, Cleveland, 1955; E. M. K. Geiling, Chicago, 1956; Elmer M. Nelson, Washington, D. C., 1956; Henry K. Beecher, Boston, 1956; Torald Sollmann, Chairman, Cleveland, 1957; James P. Leake, Washington, D. C., 1957; C. Guy Lane, Boston, 1957; Robert T. Stormont, Secretary, Chicago.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION—M. A. Bowie, Swarthmore, Pa., 1953; Arthur L. Watkins, Boston, 1953; W. J. Zeiter, Cleveland, 1953; F. H. Krusen, Chairman, Rochester, Minn., 1954; Anthony C. Cipollaro, New York, 1954; Felix Butte, Dallas, Texas, 1954; O. Glasser, Cleveland, 1955; Shields Warren, Boston, 1955; Derrick Vail, Chicago, 1955; Frank R. Ober, Boston, 1956; D. M. Lierle, Iowa City, 1956; W. W. Coblentz, Washington, D. C., 1957; George M. Piersol, Philadelphia, 1957; Ralph E. DeForest, Secretary, Chicago.

COUNCIL ON FOODS AND NUTRITION—William J. Darby, Nashville, Tenn., 1953; C. A. Elvehjem, Madison, Wis., 1953; John B. Youmans, Nashville, Tenn., 1953; L. A. Maynard, New York, 1954; Grace Goldsmith, New Orleans, 1954; Charles S. Davidson, Boston, 1954; Clement A. Smith, Boston, 1955; C. S. Ladd, Washington, D. C., 1955; Howard B. Lewis, Chairman, Ann Arbor, Mich., 1956; George R. Cowgill, New Haven, Conn., 1956; J. S. McLester, Birmingham, Ala., 1957; James R. Wilson, Secretary, Chicago.

COUNCIL ON INDUSTRIAL HEALTH—R. T. Johnstone, Los Angeles, 1953; A. J. Lanza, Chairman, New York, 1953; C. D. Selby, Port Huron, Mich., 1953; Warren F. Draper, Washington, D. C., 1954; Henry H. Kessler, Newark, N. J., 1954; Oscar A. Sander, Milwaukee, 1954; Lloyd E. Hamlin, Chicago, 1955; Robert A. Kehoe, Cincinnati, 1955; W. P. Shepard, San Francisco, 1956; M. N. Newquist, New York, 1956; James S. Simmons, Boston, 1957; J. H. Sterner, Rochester, N. Y., 1957; C. M. Peterson, Secretary, Chicago.

COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE—Roscoe L. Sensenich, South Bend, Ind., 1953; Harold C. Lueth, Evanston, Ill., 1953; Harold S. Diehl, Minneapolis, 1954; Richard L. Meiling, Columbus, Ohio, 1954; A. A. Brindley, Toledo, Ohio, 1955; W. J. Baker, Chicago, 1955; Stafford L. Warren, Los Angeles, 1956; Herbert B. Wright, Cleveland, 1956; James C. Sargent, Chairman, Milwaukee, 1957; Perrin H. Long, Brooklyn, 1957; Mr. C. Joseph Stetler, Secretary, Chicago.

COUNCIL ON RURAL HEALTH—F. S. Crockett, Chairman, Lafayette, Ind., 1953; G. F. Bond, Bat Cave, N. C., 1953; C. S. Mundy, Toledo, Ohio, 1954; C. R. Henry, Little Rock, Ark., 1954; F. A. Humphrey, Ft. Collins, Colo., 1955; N. H. Gardner, E. Hampton, Conn., 1955; A. T. Stewart, Lubbock, Texas, 1956; J. F. Doughty, Tracy, Calif., 1956; W. J. Weese, Ontario, Ore., 1957; W. A. Wright, Williston, N. D., 1957; Mrs. A. Hibbard, Secretary, Chicago.

COMMITTEE ON MENTAL HEALTH—W. H. Baer, Peoria, Ill., 1953; L. H. Bartemeier, Chairman, Detroit, 1953; L. H. Smith, Philadelphia, 1954; M. Levine, Cincinnati, 1954; F. M. Forster, Washington, D. C., 1955; H. T. Carmichael, Chicago, 1956; M. R. Kaufman, New York, 1957; R. J. Plunkett, Secretary, Chicago.

The Secretary, Assistant Secretary and Editor are ex officio members of all Standing Committees

REGISTRATION

The Registration Bureau will be located in the St. Louis Municipal Auditorium. An information bureau will be operated in connection with the Registration Bureau.

Who May Register

Members—Active, Affiliate, Associate, Service, and Honorary—and invited guests may register for attendance at meetings.

Active members in good standing in the American Medical Association are those members of component county medical societies and of constituent state and territorial medical associations whose names are officially reported for enrolment to the Secretary of the American Medical Association by the secretaries of the constituent medical associations and who have paid their annual American Medical Association membership dues, which this year are $25, to be paid through their constituent medical associations.

Residents, interns, students, nurses, and technicians will receive cards to fill in. These cards should be presented, at the window indicated, endorsed or with a letter signed by the superintendent of the hospital or the dean of the medical school they attend.

Register Early

Members living in the St. Louis area, as well as all other physicians who are in St. Louis early, should register as soon as possible. For the convenience of St. Louis physicians and those who arrive early, the Registration Bureau will be open Monday, Nov. 30, from 10 a. m. to 4 p. m.

The names and St. Louis addresses of those who register will be included in the issue of the *Daily Bulletin* appearing the next day, and this will enable visiting physicians to find friends who have registered.

Suggestions That Will Facilitate Registration

Members who have Advance Registration Cards will be registered with little or no delay. They should fill in the following information on these advance cards *prior to registration:* Hotel and number of guests.

Present the filled in card at any window and you will receive a badge and a copy of the Official Program.

Members without Advance Registration Cards will be given blank cards to fill out and present at any window. Those having with them their 1953 American Medical Association Membership pocket cards should present them with the registration cards. This will enable the clerk to complete the registration without delay and give you a badge and a copy of the Official Program.

Registration for General Officers and Delegates

General officers of the American Medical Association and members of the House of Delegates may register for the Scientific Assembly outside the Gold Room in the Jefferson Hotel on Tuesday, Dec. 1, before registering with the Reference Committee on Credentials and are advised *not* to register at the Registration Bureau since registration cards have already been made out for their use. It will also be possible for them to register on Sunday, Nov. 29, or Monday, Nov. 30, in the office of the Secretary of the Association, which will be located in the Check Room on the same floor as the Gold Room.

This arrangement is made for the convenience of members of the House of Delegates, which will convene on Tuesday morning at 10 o'clock in the Gold Room of the Jefferson Hotel. Delegates are requested to register for the Scientific Assembly before presenting credentials to the Reference Committee on Credentials of the House of Delegates. Delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House.

Registration for Lay Executives

Lay executive secretaries of component and constituent associations may register any time Sunday, Nov. 29, or Monday, Nov. 30, in the office of the Secretary of the Association at the Jefferson Hotel or any time after 12 noon Tuesday, Dec. 1, during the time of the session, at the House of Delegates registration desk in the Jefferson Hotel.

TRANSPORTATION

Railroad or Air Travel

It is suggested that those physicians who contemplate traveling to St. Louis to attend the clinical meeting of the Association secure information concerning railroad and airplane travel directly from their local ticket agents, who are in position to give them information regarding train or plane schedules and fares. Since the meeting is being held close to the Thanksgiving Holiday, when travel will be heavy, reservations should be made promptly.

ST. LOUIS HOTELS

If hotel reservations have not yet been secured by physicians, other than Delegates or Officers of the Association, who expect to attend the St. Louis meeting, it is suggested that such physicians fill in and send directly to the Chairman of the SUBCOMMITTEE ON HOTELS, Room 406, 911 Locust Street, St. Louis 1, Mo., the application form which may be found on advertising page 99 of this issue of THE JOURNAL. Please do not send applications for hotel reservations to the Association offices in Chicago.

MEETING PLACES

(See the street map on advertising page 99 in this issue of THE JOURNAL.*)*

GENERAL HEADQUARTERS, REGISTRATION BUREAU, SCIENTIFIC EXHIBIT, TECHNICAL EXHIBITS AND INFORMATION BUREAU: St. Louis Municipal Auditorium.

HOUSE OF DELEGATES: Gold Room, Jefferson Hotel.

SCIENTIFIC MEETINGS: St. Louis Municipal Auditorium. St. Louis Municipal Auditorium is located on Fourteenth Street at Market Street.

ENTERTAINMENT

The Subcommittee on Woman's Auxiliary of the St. Louis Medical Society is making plans for the entertainment of visiting women. A special program probably will be set up for Wednesday afternoon, Dec. 2.

Details of the proposed Wednesday afternoon program and other information of interest to visitors will be available at the Woman's Auxiliary Information Booth, which will be located near the Registration Bureau in the St. Louis Municipal Auditorium.

Gene B. Starkloff

HOUSE OF DELEGATES

The House of Delegates will meet at 10 a. m., Tuesday, Dec. 1, 1953, in the Gold Room of the Jefferson Hotel.

The Reference Committee on Credentials will meet in the Lobby just outside the Gold Room at 8:30 a. m., Tuesday, Dec. 1, 1953. *Credentials should be presented to the Reference Committee on Credentials as early as possible, so that the official roll of the House may be made up and so that the House of Delegates may organize promptly and proceed with its business.* The Reference Committee on Credentials will also meet preceding each subsequent meeting of the House of Delegates.

Each delegate should present properly executed credentials signed by the president or secretary of the constituent association or by the chairman or secretary of the section he represents. Alternates presenting credentials should see that the delegates whose places they are to take have signed the alternate authorization.

Each delegate, *before* registering with the Reference Committee on Credentials, should register for the Scientific Assembly at a desk located in the Lobby near the Gold Room. Rooms have been provided for the use of committees of the House of Delegates. Reference committees are urged to have their meetings in these rooms and to announce the time of their meetings, so that any who are interested in referred matters may be able to appear before the committees.

Typists will be at the service of the members of the House of Delegates for preparing official reports, resolutions and motions in the Check Room, which is in close proximity to the Gold Room.

REFERENCE COMMITTEES OF THE HOUSE OF DELEGATES

The Speaker of the House of Delegates of the American Medical Association, Dr. James R. Reuling, New York, has appointed delegates to serve on the reference committees of the House at the St. Louis Meeting, as follows:

Amendments to the Constitution and Bylaws

William L. Benedict, *Chairman*, Section on Ophthalmology
Frank J. Elias, Minnesota
Charles L. Farrell, Rhode Island
William M. Skipp, Ohio
Deering G. Smith, New Hampshire

Board of Trustees and Secretary, Reports of

John J. Masterson, *Chairman*, New York
James Q. Graves, Louisiana
Gordon F. Harkness, Section on Laryngology, Otology, and Rhinology
L. Howard Schriver, Ohio
Norman A. Welch, Massachusetts

Credentials

Walter E. Vest, *Chairman*, West Virginia
Vincent W. Archer, Virginia
Thomas M. d'Angelo, New York
Harlan English, Illinois
James P. Hammond, Vermont

Executive Session

Joseph D. McCarthy, *Chairman*, Nebraska
Reuben B. Chrisman Jr., Florida
Lawrence R. Dame, Massachusetts
John S. DeTar, Michigan
Peter M. Murray, New York

Hygiene and Public Health

Thurman B. Givan, *Chairman*, New York
Jay J. Crane, Section on Urology
William L. Estes Jr., Pennsylvania
Hoyt B. Woolley, Idaho
Stanley B. Weld, Connecticut

Industrial Health

Donald Cass, *Chairman*, California
William R. Brooksher, Arkansas
James Stevenson, Oklahoma
William Weston Jr., South Carolina
Dexter H. Witte, Wisconsin

Insurance and Medical Service

John M. Porter, *Chairman*, Kansas
Eustace A. Allen, Georgia
Henry S. Ruth, Section on Anesthesiology
Robert B. Wood, Tennessee
Willard A. Wright, North Dakota

Legislation and Public Relations

Bruce Underwood, *Chairman*, Kentucky
R. B. Homan Jr., Texas
J. Stanley Kenney, New York
H. Kenneth Scatliff, Illinois
C. F. Strosnider, North Carolina

Medical Education and Hospitals

James Z. Appel, *Chairman*, Pennsylvania
Warde B. Allan, Maryland
Warren W. Furey, Illinois
Charles T. Stone Sr., Section on Internal Medicine
Dwight L. Wilbur, California

Medical Military Affairs

William A. Hyland, *Chairman*, Michigan
H. Russell Brown, South Dakota
Donald C. Conzett, Iowa
J. Lafe Ludwig, California
Wendell C. Stover, Indiana

Miscellaneous Business

H. Gordon MacLean, *Chairman*, California
J. Wallace Hurff, New Jersey
Harold B. Gardner, Pennsylvania
Truman C. Terrell, Texas
Martyn A. Vickers, Maine

Reports of Officers

George M. Fister, *Chairman*, Utah
Maurice J. Dattelbaum, New York
J. Paul Jones, Alabama
William H. Halley, Colorado
George A. Woodhouse, Ohio

Rules and Order of Business

Joseph B. Copeland, *Chairman*, Texas
Herbert H. Bauckus, New York
William W. Baum, Oregon
Edward L. Compere, Section on Orthopedic Surgery
O. J. Campbell, Minnesota

Sections and Section Work

Jesse D. Hamer, *Chairman*, Arizona
W. Andrew Bunten, Wyoming
Raymond F. Peterson, Montana
J. Mather Pfeiffenberger, Illinois
David W. Gaiser, Washington

Tellers

Carrington Williams Sr., *Chairman*, Virginia
William F. Brennan, Pennsylvania
Raymond T. Holden, District of Columbia
Frank A. MacDonald, California
Rolla B. Wray, Missouri

Sergeants-at-Arms

Louis W. Jones, *Master Sergeant*, Pennsylvania
John F. Lucas, Mississippi
Karl R. Ruddell, Indiana

MEETING ROOMS OF REFERENCE COMMITTEES

Reference Committee on—

Amendments to the Constitution and Bylaws	Room 8

MEMBERS OF HOUSE OF DELEGATES CLINICAL MEETING, 1953

Following is a list of members of the House of Delegates:

DELEGATES FROM CONSTITUENT ASSOCIATIONS

ALABAMA
J. Paul Jones, Camden
E. Bryce Robinson Jr., Fairfield

ARIZONA
Jesse D. Hamer, Phoenix

ARKANSAS
William R. Brooksher, Fort Smith

CALIFORNIA
Robertson Ward, San Francisco
Samuel J. McClendon, San Diego
Eugene F. Hoffman, Los Angeles
John Winston Green, Vallejo
Lewis A. Alesen, Los Angeles
Frank A. MacDonald, Sacramento
H. Gordon MacLean, Oakland
E. Vincent Askey, Los Angeles
Dwight L. Wilbur, San Francisco
Donald Cass, Los Angeles
J. Lafe Ludwig, Los Angeles
R. Stanley Kneeshaw, San Jose

COLORADO
George A. Unfug, Pueblo
William H. Halley, Denver

CONNECTICUT
Thomas J. Danaher, Torrington
Oliver L. Stringfield, Stamford
Stanley B. Weld, Hartford

DELAWARE
Henry T. McGuire, New Castle

DISTRICT OF COLUMBIA
Hugh H. Hussey, Washington
Raymond T. Holden, Washington

FLORIDA
Louis M. Orr II, Orlando
Reuben B. Chrisman Jr., Miami

GEORGIA
Charles H. Richardson Sr., Macon
Eustace A. Allen, Atlanta

IDAHO
H. B. Woolley, Idaho Falls

ILLINOIS
H. Kenneth Scatliff, Chicago
Fred H. Muller, Chicago
J. Mather Pfeiffenberger, Alton
Harlan English, Danville
Everett P. Coleman, Canton
Percy E. Hopkins, Chicago
Warren W. Furey, Chicago
Charles H. Phifer, Chicago
Bernard Klein, Joliet
B. E. Montgomery, Harrisburg

INDIANA
Karl R. Ruddell, Indianapolis
Wendell C. Stover, Boonville
Cleon A. Nafe, Indianapolis
Eli S. Jones, Hammond

IOWA
Gerald V. Caughlan, Council Bluffs
George Braunlich, Davenport
Donald C. Conzett, Dubuque

KANSAS
John M. Porter, Concordia
Laurence S. Nelson Sr., Salina

KENTUCKY
Bruce Underwood, Louisville
Clark Bailey, Harlan

LOUISIANA
James Q. Graves, Monroe
Val H. Fuchs, New Orleans

MAINE
Martyn A. Vickers, Bangor

MARYLAND
John W. Parsons, Baltimore
Warde B. Allan, Baltimore

MASSACHUSETTS
Charles G. Hayden, Boston
Lawrence R. Dame, Greenfield
Philip S. Foisie, Boston
Earle M. Chapman, Boston
Norman A. Welch, Boston

MICHIGAN
Ralph A. Johnson, Detroit
William A. Hyland, Grand Rapids
John S. DeTar, Milan
Wyman D. Barrett, Detroit
Willis H. Huron, Iron Mountain
Robert L. Novy, Detroit

MINNESOTA
Orwood J. Campbell, Minneapolis
George A. Earl, St. Paul
J. Arnold Bargen, Rochester
Frank J. Elias, Duluth

MISSISSIPPI
John P. Culpepper, Hattiesburg
John F. Lucas, Greenwood

MISSOURI
Robert E. Schlueter, St. Louis
Rolla B. Wray, Nevada
Paul Baldwin, Kennett
Arthur S. Bristow, Princeton

MONTANA
Raymond F. Peterson, Butte

NEBRASKA
Karl S. J. Hohlen, Lincoln
Joseph D. McCarthy, Omaha

NEVADA
Wesley W. Hall, Reno

NEW HAMPSHIRE
Deering G. Smith, Nashua

NEW JERSEY
Joseph F. Londrigan, Hoboken
William F. Costello, Dover
J. Wallace Hurff, Newark
Elmer P. Weigel, Plainfield
L. Samuel Sica, Trenton

NEW MEXICO
Carl H. Gellenthien, Valmora

NEW YORK
J. Stanley Kenney, New York
John J. Masterson, Brooklyn
Maurice J. Dattelbaum, Brooklyn
Peter M. Murray, New York
George W. Kosmak, New York
A. H. Aaron, Buffalo
R. J. Azzari, New York
Edward T. Wentworth, Rochester
Thomas M. D'Angelo, Jackson Heights
Harold F. R. Brown, Buffalo
John J. H. Keating, New York
Walter P. Anderton, New York
James R. Reuling, Bayside
Carlton E. Wertz, Buffalo
Edward P. Flood, New York
Herbert H. Bauckus, Buffalo
Thurman B. Givan, Brooklyn

NORTH CAROLINA
Charles F. Strosnider, Goldsboro
B. O. Edwards, Asheville
Millard D. Hill, Raleigh

NORTH DAKOTA
Willard A. Wright, Williston

OHIO
L. Howard Schriver, Cincinnati
Clifford C. Sherburne, Columbus
Arthur A. Brindley, Toledo
Carl A. Lincke, Carrollton
William M. Skipp, Youngstown
George A. Woodhouse, Pleasant Hill
Herbert B. Wright, Cleveland

OKLAHOMA
John F. Burton, Oklahoma City
James Stevenson, Tulsa

OREGON
William W. Baum, Salem
Raymond M. McKeown, Coos Bay

PENNSYLVANIA
William L. Estes Jr., Bethlehem
James L. Whitehill, Rochester
George S. Klump, Williamsport
Elmer Hess, Erie
James Z. Appel, Lancaster
Harold B. Gardner, Harrisburg
Charles L. Shafer, Kingston
Howard K. Petry, Harrisburg
G. C. Engel, Philadelphia
Louis W. Jones, Wilkes-Barre
William F. Brennan, Pittsburgh

RHODE ISLAND
Charles L. Farrell, Pawtucket

SOUTH CAROLINA
Joseph D. Guess, Greenville
William Weston Jr., Columbia

SOUTH DAKOTA
H. Russell Brown, Watertown

TENNESSEE
William C. Chaney, Memphis
Charles M. Hamilton, Nashville
Robert B. Wood, Knoxville

TEXAS
Truman C. Terrell, Fort Worth
Milford O. Rouse, Dallas
Joseph B. Copeland, San Antonio
Arthur C. Scott Jr., Temple
John K. Glen, Houston
Robert B. Homan Jr., El Paso

UTAH
George M. Fister, Ogden

VERMONT
James P. Hammond, Bennington

VIRGINIA
Vincent W. Archer, Charlottesville
Carrington Williams Sr., Richmond
Malcolm H. Harris, West Point

WASHINGTON
David W. Gaiser, Spokane
R. A. Benson, Bremerton
Raymond L. Zech, Seattle

WEST VIRGINIA
Frank J. Holroyd, Princeton
Walter E. Vest, Huntington

WISCONSIN
William D. Stovall, Madison
Stephen E. Gavin, Fond du Lac
Dexter H. Witte, Milwaukee

WYOMING
W. Andrew Bunten, Cheyenne

HAWAII
Homer M. Izumi, Honolulu

ISTHMIAN CANAL ZONE
Norman W. Elton, Army Chemical Center, Maryland

PUERTO RICO
F. Sanchez-Castano, Vega Baja

DELEGATES FROM THE SECTIONS AND GOVERNMENT SERVICES

ANESTHESIOLOGY
Henry S. Ruth, Philadelphia

DERMATOLOGY AND SYPHILOLOGY
Robert R. Kierland, Rochester, Minn.

DISEASES OF THE CHEST
Hollis E. Johnson, Nashville, Tenn.

EXPERIMENTAL MEDICINE AND THERAPEUTICS
Charles M. Gruber, Philadelphia

GASTROENTEROLOGY AND PROCTOLOGY
Louis A. Buie, Rochester, Minn.

GENERAL PRACTICE
Paul A. Davis, Akron, Ohio

INTERNAL MEDICINE
Charles T. Stone Sr., Galveston, Texas

LARYNGOLOGY, OTOLOGY AND RHINOLOGY
Gordon F. Harkness, Davenport, Iowa

MILITARY MEDICINE
Russel V. Lee, Palo Alto, Calif.

NERVOUS AND MENTAL DISEASES
Hans H. Reese, Madison, Wis.

OBSTETRICS AND GYNECOLOGY
Harvey B. Matthews, Brooklyn

OPHTHALMOLOGY
William L. Benedict, Rochester, Minn.

ORTHOPEDIC SURGERY
Edward L. Compere, Chicago

Ferdinand C. Helwig, Maxwell G. Berry, and John H. Mayer Jr., Kansas City, Mo.

Thursday afternoon, Dec. 3

Samuel B. Grant, St. Louis, Presiding

3:00-3:30 **Hematologic Reactions to Drugs.** F. J. Heck, Rochester, Minn.

3:30-4:00 **Allergic Reactions to Drugs.** Harry L. Alexander, St. Louis.

4:00-4:30 **The Toxic Effects of Placebo Administration.** Stewart G. Wolf, Oklahoma City.

4:30-5:00 **The Role of Intravenous Carbohydrate in the Treatment of Diabetic Ketosis.** William H. Daughaday, and Marvin Rosecan, St. Louis.

ARTHRITIS: IN COMMITTEE ROOM B

Wednesday morning, Dec. 2

R. Emmet Kelly, St. Louis, Presiding

Chronic Arthritis

9:00-9:30 **Classification and Diagnosis.** C. H. Slocumb, Rochester, Minn.

9:30-10:00 **Physical Medicine.** Sedgwick Mead, St. Louis.

10:00-10:30 **Hormone Therapy.** E. F. Rosenberg, Chicago.

10:30-11:00 Intermission.

Robert C. McElvain, St. Louis, Presiding

11:00-11:30 **Orthopedic Management.** Robert M. O'Brien, St. Louis.

11:30-12:00 **Drugs and Vaccine Therapy.** Henry Rosenfeld, St. Louis.

Thursday afternoon, Dec. 3

Carl F. Vohs, St. Louis, Presiding

3:00-3:30 **Recent Advances in Diagnosis and Treatment of Gout.** Paul O. Hageman, St. Louis.

3:30-4:00 **Recent Advances in Diagnosis and Treatment of Rheumatic Fever.** Robert J. Glaser, St. Louis.

4:00-4:30 **Practical Advances in Rehabilitation of the Arthritic.** D. Elliott O'Reilly, St. Louis.

4:30-5:00 **Shoulder-Hand Syndrome in Related Disorders.** Otto Steinbrocker, New York.

PEDIATRICS: IN ASSEMBLY HALL 4

Wednesday morning, Dec. 2

Joseph C. Jaudon, St. Louis, Presiding

9:00- 9:30 **The Diagnosis and Management of Bacterial Meningitis.** Fred G. Burke, Washington, D. C.

9:30-10:00 **The Diagnosis and Management of Aseptic Meningitis Syndrome in Children.** Alex J. Steigman, Louisville, Ky.

10:00-10:30 **The Diagnosis and Management of Cerebral Palsy.** M. A. Perlstein, Chicago.

10:30-11:00 *Intermission.*

Guy N. Magness, University City, Mo., Presiding

11:00-11:30 **The Role of Physical Medicine in the Care of Cerebral Palsy.** Sedgwick Mead, St. Louis.

11:30-12:00 **Subdermal Hematomas in Infancy.**
Robert D. Mercer, Cleveland.

IN COMMITTEE ROOM B

Wednesday afternoon, Dec. 2

Peter G. Danis, St. Louis, Presiding

3:00- 3:25 **Conditions Which Stimulate Leukemia.**
S. D. Mills, Rochester, Minn.

3:25- 3:50 **The Management of Acute Leukemia.**
James P. King, St. Louis.

3:50- 4:15 **The Management of Erythroblastosis Foetalis in Relationship to Recent Knowledge.**
Fred H. Allen Jr., Boston.

4:15- 4:40 **The Diagnosis and Management of Bleeding Tendencies in Children.**
W. G. Rice, St. Louis.

4:40- 5:00 **Questions from the Floor.**

IN ASSEMBLY HALL 4

Thursday afternoon, Dec. 3

Max Deutch, St. Louis, Presiding
Acute Rheumatic Fever in Childhood:
C. P. Lynxwiler, St. Louis, Moderator

3:00- 3:30 **Diagnosis of Acute Rheumatic Fever.**
Arild E. Hansen, Galveston, Texas.

3:30- 4:00 **The Treatment of Rheumatic Fever.**
David Goldring, St. Louis.

4:00- 4:30 **Open Discussion with Questions from the Floor.**

4:30- 5:00 **The Management of Common Congenital Deformities of the Head and Neck.**
James F. Dowd, St. Louis.

CARDIOVASCULAR DISEASES: IN ASSEMBLY HALL 3

Tuesday afternoon, Dec. 1

Paul S. Barker, Ann Arbor, Mich., and
John R. Smith, St. Louis, Presiding

3:00- 3:30 **Peripheral Vascular Diseases and Their Cure.**
Isidor Mufson, New York.

3:30- 4:00 **Coronary Heart Disease and Angina Pectoris.**
Paul S. Barker, Ann Arbor, Mich., Moderator
Drew Luten, St. Louis,
Isidor Mufson, New York,
E. Sterling Nichol, Miami, Fla., and
James G. Janney Jr., St. Louis.

4:30- 5:00 **Gadgetless Cardiology.**
Arthur E. Strauss, St. Louis.

Wednesday morning, Dec. 2

F. Stanley Morest, Kansas City, Mo., *Presiding*

9:00- 9:30 **Use of Anticoagulants in Heart Disease: The First Decade.**
E. Sterling Nichol, Miami, Fla.

9:30-10:30 **Modern Concepts in Management of Hypertension.**
Henry A. Schroeder, St. Louis, Moderator
Dean F. Davies, St. Louis,
Sibley W. Hoobler, Ann Arbor, Mich.,
Edmund A. Smolik, St. Louis, and
Robert W. Wilkins, Boston.

10:30-11:00 Intermission.

J. William Fleming Jr., Moberly, Mo., Presiding

11:00-12:00 **Rheumatic Fever and Rheumatic Heart Disease.**
Lawrence I. Kahn, Clayton, Mo., and
Wright R. Adams, Chicago.

Wednesday afternoon, Dec. 2

David B. Flavan, St. Louis, Presiding

3:00- 4:00 ***The Cyanotic Child.***
C. Robert E. Wells, Philadelphia, and
Willis J. Potts, Chicago.

4:00- 5:00 **Joint Program with Obstetrics and Gynecology. Heart Disease in Pregnancy.**
Julius Jensen, St. Louis, and Willis E. Brown, Little Rock, Ark.

Thursday afternoon, Dec. 3

Thomas H. Burford, St. Louis, Presiding

3:00- 3:30 **The Cardiac Patient as a Surgical Risk.**
Seymour Brown, St. Louis.

3:30- 4:00 **Cardiac Arrest.**
Brian B. Blades, Washington, D. C.

4:00- 5:00 **Joint Program with Surgery.**
The Mitral Problem.
Lewis E. January, Iowa City,
Michael E. DeBakey, Houston, Texas, and
Denton A. Cooley, Houston, Texas.

PULMONARY DISEASES: IN COMMITTEE ROOM B

Tuesday afternoon, Dec. 1

Paul Murphy, St. Louis, *Presiding*

3:00- 3:30 **Processing the Patient with a Positive Chest Film.** John H. Skavlem, Cincinnati.

3:30- 4:00 **The Palliative Management of Intrathoracic Malignancy.** Duane M. Carr, Memphis, Tenn.

4:00- 4:30 **Crush Injuries of the Chest.**
John F. Neville Jr., St. Louis.

4:30- 5:00 **Sclerosing Pneumonitis.**
Joseph L. Lucido, St. Louis.

Thursday morning, Dec. 3

E. E. Glenn, Springfield, Mo., Presiding

9:00- 9:30 **Pulmonary Function Tests.**
Herbert C. Sweet, St. Louis.

9:30-10:00 **Cancer of the Lung.**
O. T. Claggett, Rochester, Minn.

10:00-10:30 **Pulmonary Manifestations in Disseminated Lupus.**
Philip A. Tumulty, St. Louis.

10:30-11:00 Intermission.

Lawrence E. Wood, Kansas City, Mo., Presiding

11:00-11:30 **The Present Status of Our Tuberculosis Problem.**
George D. Kettelkamp, Koch, Mo.

11:30-12:00 **The Current Treatment of Pulmonary Tuberculosis.** James J. Waring, Denver.

GASTROINTESTINAL DISEASES: IN COMMITTEE ROOM C

Wednesday afternoon, Dec. 2

Joseph W. Larimore and Robert W. Kelley, St. Louis, Presiding

3:00- 3:30 **A Critical Analysis of the Role of the Hormones in Digestive Tract Disease.**
J. Arnold Bargen, Rochester, Minn.

3:30- 4:00 **Surgical Care of Ulcerative Colitis.**
Richard K. Gilchrist, Chicago.

4:00- 4:30 **The Evaluation of Early Diagnostic Procedures in Massive Gastrointestinal Hemorrhage.**
Albert E. Stock and William A. Knight Jr., St. Louis.

4:30- 5:00 **Chronic Pancreatitis.** Robert Elman, St. Louis.

IN ASSEMBLY HALL 3

Thursday morning, Dec. 3

Emmet D. Wall, St. Louis, Presiding

9:00- 9:30 **Radiological Study of Lesions of the Stomach.**
Gladden V. Elliott, St. Louis.

9:30-10:00 **The Problem of Chronic Ulcerative Colitis.**
Joseph B. Kirsner, Chicago.

10:00-10:30 **The Role of Cortisone and ACTH in Gastrointestinal Lesions.**
H. Marvin Pollard, Ann Arbor, Mich.

10:30-11:00 Intermission.

Bruce D. Kenamore, St. Louis, Presiding

11:00-11:30 **Studies on Gastric Surgery.**
Donovan C. Browne, New Orleans.

11:30-12:00 **Changes in Surgery in Carcinoma of the Stomach: 1940-1953.**
C. H. Brown, Cleveland.

DERMATOLOGY: IN COMMITTEE ROOM C

Wednesday morning, Dec. 2

Garold V. Stryker, St. Louis, Presiding

9:00-10:00 **Panel: "Do's and Don'ts" in Dermatology.**
Clinton W. Lane, St. Louis, Moderator
Joseph B. Grindon Jr., M. D. Marcus, George A. Manting, and Newell W. Schlueter, St. Louis.

10:00-10:30 **Occupational Dermatitis.**
Leonard F. Weber, Chicago.

10:30-11:00 Intermission.

Norman Tobias, St. Louis, Presiding

11:00-11:30 **Dermatologic Manifestations of Hypoproteinemia.**
David B. Morgan, Kansas City, Mo.

11:30-12:00 **Weed Poisoning.**
W. E. Wooldridge, Springfield, Mo.

Thursday afternoon, Dec. 3

Richard S. Weiss, St. Louis, Presiding

3:00- 4:00 **Panel: Moles and Birthmarks.**
George C. Andrews, New York, Moderator
James W. Bagby, Martin F. Engman Jr., Minot P. Fryer, Hyman J. Goldman, and Arthur W. Neilson, St. Louis.

4:00- 4:30 **Insect Bites.**
Herman V. Allington, Oakland, Calif.

4:30- 5:00 **The Triad of Staphylococcic-Seborrheic Dermatitis, Allergic Dermatitis, and Psychogenic Dermatitis.**
Willliam J. Morginson, Salt Lake City.

NEUROLOGY AND PSYCHIATRY: IN COMMITTEE ROOM C

Tuesday afternoon, Dec. 1

Edwin F. Gildea, St. Louis, Presiding

3:00- 3:20 **Strokes: Differential Diagnosis.**
Adolph L. Sahs, Iowa City.

3:20- 3:40 **Aging Patterns in Cerebral Arteries: Their Significance in the Genesis of Arteriosclerosis.**
Herman T. Blumenthal, St. Louis.

3:40- 4:00 **Brain Tumor: Symptoms and Signs.**
Henry G. Schwartz, St. Louis.

4:00- 4:20 **Clinical Significance of the Electroencephalogram.**
James L. O'Leary, St. Louis.

4:20- 4:40 **Thyroid Disease and the Nervous System.**
Irwin Levy, St. Louis.

4:40- 5:00 **The Mechanism of the Neurological Symptoms and Signs in Spondylolisthesis.**
Robert D. Woolsey, St. Louis.

Thursday morning, Dec. 3

Louis H. Kohler, St. Louis, Presiding

9:00- 9:20 **Anxiety Heart Disease: Description and Treatment.**
Jackson A. Smith and Don W. Chapman, Houston, Texas.

9:20-10:00 **The Doctor's Role in the Preservation of Mental Health.**
Frank F. Tallman, Sacramento, Calif.

10:00-10:30 **Management of Attempted Suicide.**
Edwin H. Schmidt Jr., Patricia O'Neal, and Eli Robins, St. Louis.

10:30-11:00 Intermission.

Albert T. Steegmann, Kansas City, Kan., and
Robert E. Britt, St. Louis, Presiding

11:00-11:30 **The Psychology of Food Intake as It Relates to Underweight and Obesity.**
O. Spurgeon English and H. Keith Fischer, Philadelphia.

11:30-12:00 **A Usable Framework for the Practice of Comprehensive Medicine.**
George Saslow, St. Louis.

COLOR TELEVISION PROGRAM

In Cooperation with Smith, Kline and French Laboratories

ST. LOUIS MUNICIPAL AUDITORIUM: ASSEMBLY HALL 1

Tuesday afternoon, Dec. 1

3:00- 3:02 **Introduction and Welcome.**
Harry K. Purcell.

Moderators: Robert J. Glaser and David T. Graham

3:02- 3:25 **Technique of Bronchography.**
Alfred Goldman and David N. Kerr.

3:25- 3:45 **Examination of the Musculo-Skeletal System.**
Paul O. Hagemann.

3:45- 4:10 **Aerosol Detergents and Enzymes in the Treatment of Bronchial Asthma.**
Samuel C. Bukantz and Douglas W. Eastwood.

4:10- 4:30 **Localization of Brain Tumors with Radioactive Isotopes.**
William B. Seaman and Michel M. Ter-Pogossian.

4:30- 4:50 **Screening Procedures for Detection of Fat and Occult Blood in the Stools.**
Albert I. Mendeloff.

Wednesday morning, Dec. 2

Moderators: Harry K. Purcell and Jerome I. Simon

9:30-10:00 **Vein Stripping.** Charles R. Doyle.

10:00-10:10 **The Indications for Hysterectomy.**
Leo J. Hartnett.

10:10-10:40 **Abdominal Hysterectomy.** James Pennoyer.

10:40-10:50 **Injuries to the Common Duct.**
Gene B. Starkloff.

10:50-11:20 **Cholecystectomy.** Charles S. Sherwin.

11:20-11:25 **Comments on Anesthesia in Abdominal Surgery.**
Harry C. Sammons.

11:25-11:35 **Circumcision.** William F. Melick.

Wednesday afternoon, Dec. 2

Moderators: Lee T. Ford and R. H. Ramsey

3:00- 3:40 **The Interpretation and Demonstration of Orthopedic Procedures Relative to the Back.**
J. Otto Lottes, Donald O. Burst, and Vilray P. Blair Jr.

3:40- 4:15 **The Diagnosis of Peripheral Vascular Disease.**
Morton D. Pareira.

4:15- 4:50 **Clinic on Rehabilitation.**
Sedgwick Mead and D. Elliott O'Reilly.

4:50- 5:10 **The Management of Common Eye Disorders.**
Daniel Bisno.

Thursday morning, Dec. 3

Moderators: Roland S. Kieffer and
Joseph E. Von Kaenel

9:30- 9:45 **Diagnostic Techniques in Evaluation of Patients for Cardiac Surgery.** Bernard A. Bercu.

9:45-10:25 **Mitral Valvulotomy.** C. Rollins Hanlon.

10:25-10:35 **The Indications for Mitral Valvulotomy.**
C. Rollins Hanlon.

10:35-11:05 **Inguinal Herniorrhaphy.**
Joseph C. Peden Jr. and Carl E. Lischer.

11:05-11:15 **The Indications for Thyroidectomy.**
Bernard L. Sinner.

11:15-11:45 **Thyroidectomy.** Heinz Haffner.

Thursday afternoon, Dec. 3

Moderators: William A. Knight Jr. and
James G. Janney Jr.

3:00- 3:25 **The Problems in Present Day Control of Syphilis.**
Arthur W. Neilson.

3:25- 3:45 **The Problems of Growth and Development.**
Peter G. Danis.

3:45- 4:10 **Demonstration and Interpretation of Normal and Abnormal Neurological Findings.**
Louis L. Tureen.

4:10- 4:30 **Dermatology Clinic.** Louis Keller.

4:30- 4:50 **Recent Advances in the Management of Lymphoma.** G. O. Broun Sr.

4:50- 5:15 **Demonstration of Guides in the Choice of Antibiotic Therapy of Respiratory Tract Infections.** T. Van Metre.

Friday morning, Dec. 4

Moderators: James E. Lewis and
Vencel W. Hollo

9:30-10:00 **Nephrectomy.** Edward M. Cannon.

10:00-10:10 **The Diagnosis of Breast Lumps.**
Eugene M. Bricker.

10:10-10:40 **Radical Mastectomy.** C. Alan McAfee.

10:40-10:50 **The Indications for Gastrectomy in Duodenal Ulcer.** Charles L. Eckert.

10:50-11:30 **Subtotal Gastrectomy.** F. Eugene Pennington.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will be located in Convention Hall on the second floor of Kiel Auditorium, directly above the Technical Exposition. It may be reached by ramps and stairways and by elevator adjacent to the Registration Desks.

The Committee on Scientific Exhibit has arranged several special features, including the manikin demonstrations on problems of delivery, the exhibit symposium on traffic accidents, an extensive exhibit and a question and answer conference on diabetes, and the special exhibit on fractures.

The Scientific Exhibit will open Tuesday morning, Dec. 1, at 9:00 a. m. and will close Friday, Dec. 5, at 12:00 noon. On the intervening days, it will be open from 8:30 a. m. to 5:30 p. m.

The office of the Committee on Scientific Exhibit will be located in space 103 in the Scientific Exhibit.

Committee on Scientific Exhibit

Leonard W. Larson, Bismarck, N. D., Chairman.
James R. McVay, Kansas City, Mo.
Julian P. Price, Florence, S. C.
Thomas G. Hull, Chicago, Director

Problems of Delivery—Manikin Demonstrations

Manikin demonstrations on problems of delivery will be conducted at stated intervals throughout the week by a group of outstanding obstetricians. An opportunity for questions and discussion will be given during each demonstration.

Richard Paddock, Washington University School of Medicine, St. Louis, is chairman of the group in charge of demonstrations. Demonstrations will take place at the following hours:

Tuesday, Dec. 1, 10:00 a. m., 12:00 noon, 2:30 p. m.
Wednesday, Dec. 2, 10:00 a. m., 12:00 noon, 2:30 p. m.
Thursday, Dec. 3, 12:00 noon, 2:30 p. m., 4:30 p. m.
Friday, Dec. 4, 10:00 a. m.

The following obstetricians from St. Louis University School of Medicine and/or Washington University School of Medicine, St. Louis, will conduct the demonstrations:

Roy V. Boedeker
Carl J. Dreyer
Frank P. McNalley
William H. Vogt Jr.
George J. L. Wulff

Exhibit Symposium on the Prevention of Traffic Accidents

The exhibit symposium on the prevention of traffic accidents combines the experiences of the police, the Safety Council, and the medical profession. Emphasis is placed on the responsibility of the physician in advising his patients when not to drive a motor car.

What Is Traffic Safety?

Jacob Kulowski, St. Joseph, Mo.

Since traffic is the movement or flow of persons and vehicles along a highway, traffic safety must include both human and inhuman elements for consideration. The former has been and is being emphasized in most safety programs. It is quite a simple matter to blame the driver in all traffic accidents. What about the inhuman ingredients? How much blame should rest with the poorly designed vehicles from the standpoint of safety? This phase of the problem is being at last voiced by certain well-informed citizens. Scientific investigation is in progress along these lines. It remains for physicians to assume their share of responsibility (1) by learning more about what forces are operative in traffic accidents, and (2) by agitating for safer car design. This exhibit treats of the forces involved, mechanism of the commoner injuries, and how these might be prevented.

Testing the Drinking Driver

Herman A. Heise, Milwaukee, Committee on Tests for Intoxication, National Safety Council and Committee on Medicolegal Problems, American Medical Association.

This exhibit shows the effect of alcohol related to its percentage in body fluids. Several types of apparatus that are used to determine this percentage of alcohol are presented.

Traffic Accidents Can Be Prevented

Hugh H. Waggoner, Missouri State Highway Patrol, Jefferson City, Mo.

The exhibit will present photographs, drawings, charts, and posters showing how traffic accidents can be prevented.

Operation Safety—A Safety Educational Program

David M. Baldwin and Robert G. Schmal, National Safety Council, Chicago.

The Operation Safety display depicts the role of an individual or organization in mobilizing a community for traffic safety. It shows how a year-round program of public education for traffic safety can be developed in any community with the help of Operation Safety—a complete traffic safety program issued monthly in kit form. Leaflets, posters, radio scripts, news releases, and other materials are shown, with suggestions for using them effectively.

The Indiana State Police Auto Crash Injury Research Program

Elmer Paul and John B. Klein, Indiana State Police, Indianapolis.

Photographs show various stages of accident investigation, wherein data is obtained for further research. Photographs also point out the vital importance of the medical report as required in this research.

The Physician's Responsibility in the Prevention of Traffic Accidents

Cary N. Moon Jr., Fletcher D. Woodward and Edward L. Corey, University of Virginia School of Medicine, Charlottesville, Va.

The exhibit will emphasize the responsibility of the physician in advising his patient about driving a motor car. This will include physical and mental conditions that preclude all driving, as well as instances following the administration of certain anesthetics and drugs when the patient should refrain from driving for a certain number of hours.

Diabetes

The subject of diabetes is presented by an extensive exhibit, supplemented by a question and answer conference in an adjoining room. Patients will be shown. The program is under the direction of Joslin Clinic, New England Deaconess Hospital, Boston, and the St. Louis Diabetes Association. The chairman of the group is Howard F. Root, Boston.

Diabetes Today

Howard F. Root, Elliott P. Joslin, Priscilla White, Alexander Marble, Allen P. Joslin, and Leo Krall, Joslin Clinic, Boston.

The exhibit presents changes in the small vessels of the conjunctiva in diabetic patients related to the severity and the age of diabetic patients. New data are included on the management of pregnancy in diabetic patients, particularly of the young patients with the severe type, and new data on diabetic coma and its treatment. The importance of the control of diabetes in the prevention of serious complications and particularly the prevention of the diabetes triopathy is shown. Pamphlets will be available for distribution.

Question and Answer Conference on Diabetes

The question and answer conference will be held in Committee Room A (adjoining the Scientific Exhibit) daily from 10:00 a. m. to 1:00 p. m.

Patients will be shown during the meeting. Emphasis is placed on the fact that this is a "question and answer" conference, and questions will be answered at all times. The program follows:

Tuesday, Dec. 1

10:00 a. m. Diabetic Acidosis and Its Control. Howard F. Root, Boston.
10:20 a. m. Plea for Early Diagnosis. Robert C. McElvain, St. Louis.
10:40 a. m. Diabetes History. John L. Kennedy, St. Louis.
11:00 a. m. Diagnosis in Diabetes. Howard F. Root, Boston.
11:20 a. m. Management of the New Diabetic. George A. Mahe, St. Louis.
11:40 a. m. The Changing Order in Diabetes. Howard F. Root, Boston.
12:00 noon Pregnancy and Diabetes. Priscilla White, Boston.
12:20 p. m. Key to Prevention of Diabetes—Obesity. William H. Olmsted, St. Louis.
12:40 p. m. The Insulins. Priscilla White, Boston.

Wednesday, Dec. 2

10:00 a. m. Cardiovascular Complications. Howard F. Root, Boston.
10:20 a. m. Arteriosclerosis in Intramural vs. Extramural Coronaries. Joseph C. Edwards, St. Louis.
10:40 a. m. Methods for Teaching Blind, Deaf and Handicapped Patients. Sallie Wood, St. Louis.
11:00 a. m. Children of Diabetic Mothers. Priscilla White, Boston.
11:20 a. m. Diabetes During Surgery. Henry E. Oppenheimer, St. Louis.
11:40 a. m. Diets. Howard F. Root, Boston.
12:00 noon Is The Mother of Over-Size New-Born Predisposed to Diabetes? Robert C. McElvain, St. Louis.
12:20 p.m. Necrobiosis Lipoidica and Skin Complications. Priscilla White, Boston.
12:40 p. m. Diabetic Coma: Water and Electrolytes. Howard F. Root, Boston.

Thursday, Dec. 3

10:00 a. m. Triopathy of Diabetes and Control. Howard F. Root, Boston.
10:40 a. m. The Plantar Ulcer. William H. Olmsted, St. Louis.
11:00 a. m. Childhood and Youth; Diabetic Camps. Priscilla White, Boston.
11:20 a. m. Treatment of Diabetes During Surgery. Howard F. Root, Boston.
11:40 a. m. Endocrines and Diabetes. Priscilla White, Boston.
12:00 noon Insulin Mixtures in Juvenile Diabetes. E. Paul Sheridan, Denver.
12:20 p. m. Problems in Pregnancy. Priscilla White, Boston.

Friday, Dec. 4

10:00 a. m. Hypoglycemia and Insulin. Howard F. Root, Boston.
10:20 a. m. Follow-Up Study of Five Detection Drives. Henry E. Oppenheimer, and Harold K. Roberts, St. Louis.
10:40 a. m. Management of New Diabetics. E. Paul Sheridan, Denver.
11:00 a. m. Pregnant Diabetics. Priscilla White, Boston.

Special Exhibit on Fractures

The Special Exhibit on Fractures, presented by the Fracture Exhibit Committee, includes the following subjects:

Fractures Resulting From a Fall on the Outstretched Hand
Fractures of the Lower End of the Radius
Fractures of the Ankle.

Demonstrations will be conducted daily from 9:00 a. m. to 12:00 noon and from 2:00 p. m. to 4:00 p. m. from Tuesday morning to Friday noon. Basic principles will be stressed, with particular emphasis on the interest of the physician in general practice.

Ample opportunity will be allowed for questions. Members of the committee will be present to discuss individual problems, and physicians are invited to bring roentgenograms from troublesome cases.

The Fracture Exhibit Committee is as follows:

Gordon M. Morrison, Boston, Chairman
Ralph G. Carothers, Cincinnati
Herbert W. Virgin Jr., Miami, Fla.
Kellogg Speed, Chicago, member emeritus.

An outstanding group of qualified surgeons will participate in the demonstrations:

Roy E. Brackin, Winnetka, Ill.
Clyde W. Dawson, Columbus, Ohio
Patrick C. Doran, Akron, Ohio
Theodore A. Fox, Chicago
S. S. Freedman, Lowell, Mass.
Nicholas J. Giannestras, Cincinnati
Morris E. Goldman, Lewiston, Maine
Harry B. Hall, Minneapolis
William J. Kisiel, Springfield, Mass.
Andrew R. Mailer, Madison, Wis.
James W. Martin, Omaha
John J. Milroy, Waukegan, Ill.
William R. Molony Jr., Los Angeles
Roland F. Neumann Jr., St. Louis
Col. Oscar S. Reeder, Washington, D. C.
Samuel L. Robbins, Cleveland
Edmund T. Rumble Jr., Callicoon, N. Y.
Garland F. Smith, St. Louis.

Effect of Streptomycin on the Bronchocavitary Junction and *Its Relation to Cavity Healing*

Oscar Auerbach, Harry L. Katz, and Maurice J. Small, Veterans Administration Hospital, East Orange, N. J.

By means of roentgenograms before and after courses of streptomycin, and microscopic studies of specimens resected in such cases, there is demonstrated a significant degree of epithelialization of the draining bronchus, bronchocavitary junction, and adjacent cavity wall. This material is compared with resected specimens from cases in which streptomycin was not given. Since epithelialized surfaces do not unite and heal, the therapeutic implications of this phenomenon are pointed out.

Tuberculosis Control in Illinois *State Welfare Institutions*

Otto L. Bettag and Ernest Teller, Department of Public Welfare, State of Illinois.

The tuberculosis problem in institutions reaches far beyond their walls due to frequent and close contact between the patients, their families, the hospital employees, and the community. The exhibit deals with the various aspects of tuberculosis control in large institutions, especially state mental hospitals. A short outline of the program and several charts illustrate the progress achieved in the Illinois State Welfare Institutions since 1945.

Recent Advances in the Treatment of Lung Cancer

William L. Watson, David Karnofsky, John L. Pool, William G. Cahan, Raymond K. J. Luomanen, Alexander J. Conte, and Sam H. Seal, Memorial Cancer Center and American Cancer Society, New York.

The exhibit shows the most recent surgical methods, radiation, procedures, and chemotherapeutic methods of treating lung cancer. The interdependence of these methods is demonstrated.

Foreign Bodies of the Tracheal Bronchial Tree and Esophagus

A. C. Stutsman, Washington University School of Medicine, St. Louis.

The exhibit displays roentgenograms of foreign bodies in the tracheal bronchial tree and esophagus. Some of the foreign bodies are shown mounted in plastic.

Oral Lesions

Charles K. Shofstall and William H. Shofstall, Kansas City, Mo.

This is an exhibit of colored transparencies the purpose of which is to create an interest in oral pathology and stress the importance of oral lesions as manifestations of local and systemic diseases.

Abdominal Incisions

Louis T. Palumbo and Irving A. Katz, Veterans Administration Center, Des Moines, Iowa.

The exhibit portrays the surgical anatomy and technique involved in each of the following abdominal incisions: (1) transverse, elliptical supraumbilical and infraumbilical; (2) transverse, muscle-splitting, right or left at level of umbilicus; (3) oblique, subcostal, right or left; (4) oblique, suprainguinal, left; and (5) combined thoracoabdominal, right or left. Each specific incision includes the type of surgical procedures that can be performed and the organ or organs and pathological processes that can be approached or removed through these wounds. Each incision utilized is supported by factual data, which includes the total number, wound complications, and incidence of postoperative hernia. Stress is placed upon several important factors as follows: These incisions are anatomically sound and provide excellent exposure; complications are minimized, wound separation or evisceration is almost nonexistent, and the postoperative hernia rate is extremely low.

Rehabilitation of Spinal Cord Injuries

W. Scott Allan, Liberty Mutual Insurance Company, Boston.

A series of drawings, transparencies, and photomural cutouts describe the accident, hospital care, rehabilitation therapy, and associated counseling in two selected cases of multiple injury, including spinal cord damage. Through the medium of these case histories and the facts and statistics of a general nature, the effectiveness of a specialized, coordinated program of rehabilitation is demonstrated.

Medullary Nailing for Fractures of the Shaft of the Tibia

J. Otto Lottes, Lloyd J. Hill, Stanley M. Leydig, and J. Albert Key, Washington University School of Medicine, St. Louis.

The exhibit presents 24 cases illustrating the different types of fractures of the shaft of the tibia that were treated with a triflange medullary nail. End results are shown in most of the cases and include fractures of the upper, mid, and lower third, including double and triple fractures. All fresh fractures have been nailed by the blind technique. Cases of nonunion, delayed union, and fresh fractures are shown in this series. Closed and open fractures nailed both as primary and as delayed procedures are presented. Charts show the location of the fracture sites as well as the type of fracture and the number of cases. Results of all cases in which nails were used are shown, together with the technique of blind nailing as well as of open nailing.

A Dynamic Brachial Plexus—Anatomy and Motor Function

Col. H. B. Luscombe (MC) and Capt. Joel L. Roth (MC), U. S. Army, Walter Reed Army Medical Center, Washington, D. C.

The exhibit consists of a three-dimensional anatomical demonstration of the brachial plexus and demonstrates the verbal effects of cord, root, and nerve lesions at various levels.

Reconstruction of Facial Injuries and Defects

James Barrett Brown, Minot P. Fryer, and Frank McDowell, Washington University School of Medicine, St. Louis.

Photographs of injuries and defects of the face with follow-up photographs of results of reconstructive surgery are presented. Description of internal wire fixation of fractures, composite grafts, and synthetic subcutaneous prostheses are included.

Uncommon Obstructions of the Extrahepatic Bile Ducts

Willard Bartlett, St. Louis University School of Medicine, St. Louis.

Data from personal cases of malignant and unusual nonmalignant obstructing lesions at various levels are presented in text and by color transparencies of photographs of the operative field, gross specimens, and photomicrographs, together with tabulation of statistical data from the literature as to their incidence. The data on six local adults not previously treated with surgery for benign fibrous stenosis of the extrahepatic ducts (obliterative cholangitis) have been collected by the author and are included. The importance of recognition and prompt inspection of an obstructing lesion and of avoiding an improper choice of operative procedure when such a lesion is unexpectedly encountered at exploration is stressed.

Malignant Melanoma and Moles—Clinical Diagnosis and Surgical Management

George T. Pack, I. M. Scharnagel, and Jeff Davis, Memorial Center for Cancer and Allied Diseases, New York.

The differential clinical and pathological diagnosis of malignant melanoma and moles will be presented with indications for surgical intervention and choice of procedures in particular instances. A series of scattergrams will be employed to demonstrate patterns of melanin formation and the regional distribution of benign pigmented moles in 1,000 patients, and malignant melanomas in 1,225 patients. Indications for and types of surgical procedure employed in both primary and metastatic melanoma will be illustrated by diagram and photographs. Statistics on end-results in treatment of 1,225 cases of malignant melanoma will be given.

The Control of Lip Cancer

Henry Schwarz II, José M. Sala, Vernon E. Sammons, and Joseph H. Lesser, Ellis Fischel State Cancer Hospital, Columbia, Mo.

The exhibit outlines the following points: (1) the surgical and radiotherapeutic approach to the control of the primary lip lesions; (2) the approach to the control of secondary deposits within the neck; and (3) the results of treatment at The Ellis Fischel Cancer Hospital since 1940.

Cervical Disc Lesions

J. Albert Key and Lee T. Ford, Washington University School of Medicine, St. Louis.

The exhibit outlines the key points in the diagnosis and treatment of cervical disc lesions. It points out that the treatment is most often conservative and may be carried out in most cases by the family physician.

Thyroid Tumors of Low Malignancy

V. E. Chesky, W. C. Dreese, and C. A. Hellwig, Hertzler Clinic and Hertzler Research Foundation, Halstead, Kan.

The exhibit presents an analysis of 137 cases of malignant thyroid tumors. Gross and microscopic anatomy, correlation with clinical findings, and follow-up studies are included. Treatment of the great majority of malignant thyroid tumors consists of lobectomy only. Prophylactic neck dissection in tumors of low malignancy (papilloma, Hurthle cell tumor, and invasive adenoma) is not justified.

Relationship of the Right Hepatic and Cystic Arteries to the Extrahepatic System as Seen in the Operating Room

J. Major Greene and Earle I. Greene, Cook County Hospital, Chicago Medical School, Grant Hospital and Mt. Sinai Hospital, Chicago.

Wax models diagrammatically illustrate the various locations of the right hepatic and cystic arteries in relationship to the hepatic, common, and cystic ducts. Knowledge of these abnormal locations will prevent injury to the right hepatic artery and extrahepatic system during surgery.

Testicular Tumors

Col. J. C. Kimbrough (MC) U. S. Army, Major F. E. Cook (MC), U. S. Air Force, and Capt. A. A. Borski (MC), U. S. Army, Walter Reed Army Hospital, Washington, D. C.

This exhibit emphasizes the need for early diagnosis of testicular tumors. This can be accomplished only by the routine bimanual palpation of testes. Gross and microscopic photographs of the tumors are exhibited. Radical retroperitoneal node dissection is illustrated, and the results of this form of treatment are presented in comparative tables.

Control of Cortisone Therapy in Rh Incompatibilities

Oscar B. Hunter Jr., Doctors Hospital Research Foundation and Georgetown University School of Medicine, Washington, D. C.

This exhibit outlines the theoretical considerations for the use of cortisone during pregnancies involving Rh incompatibilities, and the methods of control of proper dosage by estimation of 17-ketosteroids and pregnanediol in the urine.

Pregnancy in the Bicornuate Uterus

Frederick H. Falls, University of Illinois College of Medicine and Charlotte S. Holt, Illinois State Department of Public Health, Chicago.

The exhibit consists of sculptures, charts, drawings and x-ray translights illustrating the embryological development of the normal female genitalia and various anomalies resulting from interference with the developmental process. The comparative anatomy in other vertebrates is also shown, and the analogy between these uteri and the human bicornuate uterus is pointed out. The obstetrical complications that arise in women when such uteri become pregnant are depicted, together with suggested management.

Salpix, Ortho—A New, Water-soluble, Nonirritating X-ray Opaque Medium

I. C. Rubin, Ernst Myller, and Carl G. Hartman, Ortho Research Foundation, Raritan, N. J.

This exhibit consists of transparencies presenting (1) hysterosalpingograms showing patent as well as blocked tubes; and (2) hysterograms illustrating the adaptability of the new medium to locating lesions of the fundus, both benign and malignant.

Storage of Estrogen in Human Fat

William E. Barfield and Nelson H. Brown, Medical College of Georgia, Augusta, Ga.

Charts outline assay values for estrogens in human fat after treatment of patients with various estrogenic substances and depict rationale of treatment for menopausal patient as well as results of therapy of menopausal patients with tri-p-anisylchloroethylene. Vaginal smears before and after therapy and at various intervals after discontinuation of therapy are presented.

Modern Concepts of Endocrine Therapy in Gynecic Disorders

Herbert S. Kupperman, Stanley J. Goodman, Jay Burger, and Arthur Bernstein, Diagnostic and Endocrine Laboratories, Newark, N. J. and New York University-Bellevue Medical Center, New York.

A pictorial representation and a didactic schematic presentation of the prevailing concepts of endocrine therapy in the gynecological disturbances frequently observed in office gynecology will be shown. The proper therapeutic approach together with the prevalent etiological concepts will be presented and discussed. The methods for diagnosing and treating some of the problems in gynecology will be described in detail.

The Cytologic Approach to Gynecologic Abnormalities

E. L. Hecht and W. E. Studdiford, New York University-Bellevue Medical Center, New York.

The exhibit stresses the importance of the cytological method in gynecologic diagnosis: (1) carcinoma of the cervix, with stress on the importance of the cytological method in diagnosis of preinvasive cancer; (2) endometrial carcinoma, with stress on the newly developed technique of the endometrial aspiration smear; (3) hyperestrinism and its relation to fibromyomas, endometrial hyperplasia, carcinoma of the endometrium, and ovarian cysts and tumors (analysis of cases and kodachrome transparencies); and (4) plastic model of the female genital tract and demonstration of material and technique of taking smears.

Experiment in Treatment of Peptic Ulcer with Unrestricted Diet

Edward A. Marshall, Huron Road Hospital, East Cleveland, Ohio.

A total of 1,300 patients with x-ray evidence of ulcer have been given sufficient antacids, absorbents, and sedation to permit a full unrestricted diet without symptoms within three days. This schedule was carried out for just over four months, when all therapy was stopped and recurrence awaited, still with unrestricted diet. Results in hemorrhagic and obstructed ulcer were unusual. Follow-up showed over 50% have not had recurrence in over three years. It was felt there was some evidence that a majority of ulcers were healed during therapy. There were 28 gastrectomies in this group.

Cancer of the Stomach

Cecil O. Patterson, Milford O. Rouse, Ruth Sanders, Patricia O'Neill, and George W. Hagy, Southwestern Medical School of the University of Texas, Dallas, Texas.

This exhibit presents the problem of gastric cancer organized under three main headings of early suspicion, accurate diagnosis, and factors influencing survival and physical fitness. Material on the genetics of stomach cancer is included, as well as pertinent case histories and diagnostic data. Illustrations consist of original color drawings and charts, photographs, and transparencies.

Antacid Therapy of Peptic Ulcer

Leo L. Hardt, Frederick Steigmann, Clarence A. Maaske, and Robert Grover, Stritch School of Medicine of Loyola University, Cook County Graduate School of Medicine, Chicago, and University of Colorado School of Medicine, Denver.

A review of the rationale and development of antacids in the treatment of peptic ulcer is presented on the basis of both clinical and animal investigations. The effect of antacids and antispasmodics on motility and peptic activity is evaluated. The coating effect of some antacids as seen gastroscopically is discussed, and the possible therapeutic significance of this phenomenon evaluated. The studies on the antacid capacity of various antacids as observed in vitro and in the histamine-stimulated stomach are presented, as well as the significance of dose, mode of administration, and composition and possible side-effects of the antacids. Particular reference is given to a thixotropic gel, which has a coating effect similar to that of gastric mucin.

Aids in the Diagnosis of Benign and Malignant Ulceration of the Stomach—Gastroscopic Observation, Gastric Biopsy and Exfoliative Cytology

EMMANUEL DEUTSCH, Tufts College Medical School, Boston.

Gastroscopic observation of the presence or absence of changes in the smooth muscle layers of the stomach can help in distinguishing benign and malignant ulceration of the stomach. The changes that occur in the contour of the stomach follow the variation in contraction and relaxation of the smooth muscle layers of the gastric wall. Observation of peristaltic waves and segmental tonus changes of the stomach is of considerable value. Exfoliative cytology is a process of scraping under direct gastroscopic vision using a polyethylene tube, after which the desquamated mucosa and muscularis mucosae is aspirated and quickly prepared for cell block, then examined microscopically. Gastric biopsy specimens obtained under gastroscopic observation can be examined microscopically for definitive diagnosis.

Duodenal Intubation in Intestinal Obstruction

JOHN W. DEVINE and JOHN W. DEVINE JR., Lynchburg, Va.

A new instrument for intubating the duodenum is shown, and the technique is demonstrated. The instrument has a flexible tip control that enables the operator to insert the tube into the duodenum. Case histories showing the advantage of prompt, controlled duodenal intubation and rapid intestinal decompression using the air vent tube are presented.

Cardiac Arrest and Resuscitation in Twelve Hundred Cases—A Hospital Plan of Action

J. WILLIAM HINTON and L. CORSAN REID, New York University Post-Graduate Medical School, New York, and HUGH E. STEPHENSON JR., University of Missouri School of Medicine, Columbia, Mo.

With the use of realistic models the physician may learn the proper method of cardiac massage. The present status of cardiac resuscitation will be reviewed through the use of charts and drawings based on a detailed study of over 1,200 cases of cardiac arrest. The exhibit is designed to give the physician a more complete working knowledge through a better understanding of the physiology and pharmacology of resuscitation.

Stenotic Valvular Heart Disease—Results of Surgery

ROBERT P. GLOVER, THOMAS J. E. O'NEILL, O. HENRY JANTON, and LOUIS A. SOLOFF, Hahnemann, Episcopal, St. Christopher's for Children, Lankenau and Presbyterian hospitals, Philadelphia.

During the past five years, intracardiac surgery has passed from the exploratory, experimental stage into an universally accepted, standardized specialty with wide application. Each of the heart valves when in a state of stenosis can technically be opened. During this period of time the authors have studied and operated upon over 500 patients. It has now become clear that more than 75% of patients have shown definite improvement, in many instances of great magnitude, and the over-all operative mortality has been less than 7%. This exhibit depicts the pathology of the lesion under question and the technique of the operative approach in brief, but emphasizes the results of such surgery together with preoperative evaluation and postoperative management.

The Use of Autonomic Blocking Agents in Cardiovascular Diseases

CAPT. MARVIN MOSER (MC), U. S. Air Force, 1ST LIEUT. EDMUND H. REPPERT (MC), U. S. Army, ANDREW G. PRANDONI, and COL. THOMAS W. MATTINGLY (MC), U. S. Army, Walter Reed Army Hospital, Washington, D. C.

Results of comparative studies with hexamethonium parenterally, dibenzyline orally and parenterally, and priscoline intra-arterially on blood flow, skin temperature, and vasomotor responses in a series of patients with peripheral vascular disease are presented. An appraisal of the use of these agents in the treatment of conditions associated with (1) increased vasomotor tone, (2) the post-frostbite syndrome, (3) organic vascular disease, and (4) post-traumatic causalgia is made. They appear to have a definite but limited place in the study and treatment pain states; dibenzyline and hexamethonium proved to be especially useful. Results obtained with parenteral and oral administration of hexamethonium, apresoline, and dibenzyline, either alone or in combination, in essential, renal, and malignant hypertension as well as in the hypertension accompanying toxemia of pregnancy are summarized.

Diagnosis of Aorta-Iliac Artery Occlusion

FAY A. LEFEVRE, V. G. DEWOLFE, A. W. HUMPHRIES, E. F. POUTASSE, and J. C. ROOT, Cleveland Clinic, Cleveland.

This exhibit summarizes the study of 46 cases of obstruction of the abdominal aorta or iliac arteries. The clinical symptoms typical of this syndrome are outlined. The symptom of hip claudication, generally not recognized, is demonstrated. Twenty-nine of the 46 patients were studied by aortography. The films, with a brief history, of 12 typical cases are demonstrated. A model demonstrating the method of aortography as well as a summary of findings of the 46 cases is included.

Surgical Correction of Interatrial Septal Defects

CHARLES P. BAILEY, H. E. BOLTON, W. LIKOFF, W. L. JAMISON, and H. T. NICHOLS, Hahnemann Hospital and Medical College and The Bailey Thoracic Clinic, Philadelphia.

The exhibit demonstrates the technique for the closure of interatrial septal defects, as well as associated pulmonary-venous anomalies. The exhibit presents the surgical aspects and the results in approximately 35 cases. A very practical cardioscope is also demonstrated.

Diseases of the Mitral Valve—Diagnosis and Surgical Treatment

T. J. DRY, R. L. PARKER, J. E. EDWARDS, J. W. KIRKLIN, R. D. PRUITT, G. W. DAUGHERTY, C. H. SCHEIFLEY, A. BRUWER, R. G. TOMPKINS, and A. H. BULBULIAN, Mayo Clinic, Rochester, Minn.

Surgical treatment of mitral stenosis has been accepted as a standard procedure. Introduction of such physiological methods as cardiac catheterization has not only contributed to more accurate diagnosis but has added greatly to the understanding of the disturbed hemodynamics in mitral stenosis. This exhibit is a demonstration of (1) normal and abnormal mitral valves (stenotic, insufficient, etc.); (2) physiological data obtained by means of cardiac catheterization in mitral heart disease; (3) clinical course, diagnostic features, and differential diagnosis of mitral heart disease; and (4) indications for surgery in patients with mitral stenosis and technique of surgical treatment (commissurotomy) together with postoperative results.

Use of Intravenous Estrogens in Cardiovascular Disease

LEO GITMAN and I. J. GREENBLATT, Messinger Research Laboratory and Beth-El Hospital, Brooklyn.

The effect of intravenous administration of estrogen in degenerative cardiovascular diseases is described, with emphasis on changes in the serum beta lipoprotein and electrocardiogram.

Serum Beta Lipoprotein Studies in Hypertension and Coronary Artery Disease—A Correlative Study with the Ballistocardiogram and Electrocardiogram

THEODORE D. COHN, ROBERT A. MANDELBAUM, HARRY MANDELBAUM, and I. J. GREENBLATT, Beth-El Hospital, *Brooklyn.*

The serum beta lipoprotein of the Sf 12-20 and 20-100 groups with the ultracentrifuge technique of Gofman, was studied in 146 cases. Ballistocardiograms before and after exercise using the Dock apparatus and electrocardiographic tracings before exercise and after the one step Master's test were also performed in these cases. The study resulted in four groups according to the following factors: (1) normotension; (2) pure angina pectoris; (3) postmyocardial infarction; (4) hypertension with no angina. By use of the Sf 12-100 groups of serum beta lipoproteins as an index of atherogenesis, correlations were made of the above modalities. The data indicated evidence for use in the early diagnosis of coronary atherosclerosis.

Essential Hypertension—Diagnosis and Therapy

JOSEPH C. EDWARDS, Washington University School of Medicine, and Barnes Hospital, St. Louis.

This exhibit portrays the course of representative patients with essential hypertension of varying degrees, who have been under treatment with the hexamethonium chloride and/or 1-hydrazinophthalazine for 12 to 24 months. Directions for oral therapy and indications for parenteral therapy are given in outline form. Charts show blood pressure readings in the standing, reclining, and sitting positions of patients, in the hospital and in the office, who have been given these medications after thorough studies. Contraindications and factors to be avoided in such treatment are included, together with diagnostic criteria and methods used in treating such patients.

Vasodilating Drugs—Plethysmographic Studies—An Objective Evaluation

SAUL S. SAMUELS, Brooklyn Hebrew Hospital for the Aged, New York.

The exhibit presents the results of plethysmograph studies on the digits of patients with peripheral arterial disease to whom vasodilating drugs were administered. By means of a Winsor plethysmograph readings of pulse amplitude, skin temperature, and peripheral blood flow were recorded, yielding a purely objective evaluation of effectiveness of many available vasodilating drugs in use today.

Ballistocardiography as an Office Procedure

I. E. BUFF, Charleston, W. Va.

The use of the ballistocardiograph as a diagnostic aid in the study of cardiac disease is demonstrated by an oscilloscope, making it possible for small groups to view the procedure. The ballistocardiograph in the diagnosis of early coronary artery disease is shown. The basic principles of ballistocardiography are explained and the procedure described in detail, so that this instrument can be used in the office. Normal as well as abnormal ballistograms are included. Actual patients will be used.

Clinical Plethysmography in Peripheral Arterial Diseases

F. STANLEY MOREST, Kansas City.

A physiological approach in the study of peripheral arterial diseases can be made now by use of clinical digital plethysmography. By this method one can demonstrate the degree of arteriospasm and organic vascular disease in selecting patients for sympathectomy, and can also select that peripheral vasodilating drug which is the most efficient for the degree of arterial insufficiency present in a given patient.

A Cardiac Emergency Kit

JACOB J. SILVERMAN and MAX WERNER, Staten Island and St. Vincent's Hospitals, Staten Island, N. Y.

The average hospital emergency room today is designed primarily to handle surgical emergencies. Nevertheless, there are many cardiac conditions truly urgent that are first directed to the emergency room. Despite the brilliant advances in cardiac therapy in recent years many important drugs, some lifesaving, are not readily available. Recovery from acute cardiac conditions often depends upon the speed with which effective therapy is commenced. To facilitate the handling of cardiac emergencies there has been designed a specially constructed kit containing a supply of necessary cardiac drugs and equipment. The kit is always on hand and easily transportable, and therefore can be used throughout the hospital. The exhibit describes the kit, lists the contents, and outlines the advantages accruing from the establishment of such a kit in a hospital.

Therapeutic Equipment for Cerebral Palsy

M. A. PERLSTEIN, H. E. BARNETT, and J. G. FINDER, National Society for Crippled Children and Adults, and Michael Reese Hospital, Chicago.

The exhibit consists of miniature models of equipment used in the therapy of cerebral palsied patients, such as a stand-up table and box walker. Each model is manned by a doll manikin.

Endotracheal Anesthesia for Tonsillectomy and Adenoidectomy in Children

JOHN W. PENDER and O. E. HALLBERG, Mayo Clinic, Rochester, Minn.

The advantages of endotracheal anesthesia in adults for operation in or about the mouth have long been recognized, but this method has not been used as widely in children. Six years of experience during which endotracheal anesthesia was used routinely for tonsillectomy and adenoidectomy in children has shown that this method leads to (1) more safety for the patient, (2) better exposure of the operating field for the surgeon, and (3) more complete control of the anesthesia. The complications encountered in over a thousand children to whom endotracheal anesthesia was administered for tonsillectomy and adenoidectomy are presented. This exhibit demonstrates with models and diagram the (1) position of the endotracheal tube in relation to the surgical instruments used during various stages of the operation and (2) the equipment used and the various methods employed to deliver the anesthetic gases through the endotracheal tube to the lungs.

Treatment of Convulsive Disorders in Children

SAMUEL LIVINGSTON, The Johns Hopkins Hospital, Baltimore.

The data presented in this exhibit are based on follow-up studies of approximately 7,000 children with convulsive disorders. All of these children have been observed for a prolonged period of time, many as long as 15 to 20 years.

The Physician in Child Accident Prevention

GEORGE M. WHEATLEY, Metropolitan Life Insurance Company, New York.

The exhibit stresses the relationship of accidental injury including poisoning to the phases of growth and development of preschool and school children. It shows opportunities and techniques that practicing physicians and others can use in the study and prevention of accidents.

Congenital and Developmental Deformities of the Chest

CHARLES W. LESTER, Hospital for Special Surgery, New York.

Deformities of the chest are (1) primary, owing to malformation of the bony structure (ribs, vertebrae, and sternum) and (2) secondary, owing to defective growth and abnormal muscle pull. In the first category examples are shown of defective ribs, fused ribs, and hemivertebrae. In the latter category protrusion deformities (such as pigeon breast) and funnel chest are demonstrated, with explanation of cause and the type of surgery used when indicated.

The Mechanism of the Neurological Symptoms and Signs in Spondylolisthesis

ROBERT DEAN WOOLSEY, St. Louis University School of Medicine, St. Louis.

The exhibit is made up of charts and pictures demonstrating the anatomy of spondylolisthesis and the cause of the neurological symptoms and signs.

Control of Side-Effects of Anticonvulsant Drugs

ROBERT S. SCHWAB, JOHN A. ABBOTT, and WILLIAM H. TIMBERLAKE, Massachusetts General Hospital, Boston.

The purpose of the exhibit is to bring to the attention of physicians the possible hazards of using certain drugs in the treatment of epilepsy and the best ways to avoid various complications when these risks have to be taken. The various charts and case histories illustrate the procedure and precautions developed as safeguards in the use of drugs that carry risks. Clinical observations and examples of the so-called benign side-effects that are often encountered in the use of any drug that is taken continually by a patient through the years are shown. It is generally agreed that by the judicious use of all the known anticonvulsants at the present time, either alone or in practical combinations, the seizure incidence in over 85% of cases can be reduced.

Uses of Electroencephalogram in General Practice

JAMES L. O'LEARY, Washington University School of Medicine, St. Louis.

A series of electroencephalographic tracings with appended brief histories are presented. These illustrate the application of the electroencephalogram in determining the status of brain activity in convulsions of primary etiology, headache, vertigo, metabolic and electrolyte disturbances, and organic disease of the nervous system.

The Use of Mebaral in Alcoholism and in Anxiety

JACKSON A. SMITH, Baylor Medical College, Houston, Texas.

This exhibit describes a long-acting barbiturate that has not been habituating when used in alcoholics and that has not produced undue drowsiness when used as a daytime sedative in anxious patients. Placards describe the use, action, and dosage of this drug.

Myasthenia Gravis—Management and Diagnosis with Edrophonium Chloride (Tensilon)

KERMIT E. OSSERMAN and LAWRENCE I. KAPLAN, The Mount Sinai Hospital, New York.

The exhibit includes (1) graphic visualization of the clinical symptoms and pathological physiology of myasthenia gravis, with a summary of other diagnostic tests used; (2) pictorial and written presentation illustrating the use of edrophonium (Tensilon) for a rapid diagnostic test for myasthenia gravis suitable for office or clinic, with advantages over other diagnostic methods emphasized; (3) photographs of patients before and after intravenous administration of edrophonium; (4) outline of differential diagnosis of borderline myasthenia gravis based on the edrophonium test; and (5) the use of edrophonium chloride test for the management of the myasthenia patient to determine adequacy, inadequacy, or overtreatment with anticholinesterase drugs.

Aging (Wear and Tear) Processes in Human Cerebral Arteries

FRED P. HANDLER, J. OWEN BLACHE, and HERMAN T. BLUMENTHAL, The Jewish Hospital and St. Louis University School of Medicine, St. Louis.

This exhibit of photographs, photomicrographs, and charts shows the distribution of atheromatous plaques and their relation to vascular diameter and points of maximum wear and tear. Photomicrographs show wear and tear effects on elastic structures and the mineral changes associated with elastic fibers.

Autonomic Nervous System—The Site of Action of Various Agents

E. GREY DIMOND, KENNETH A. POWELL, and RAY EDWARD GREEN, University of Kansas Medical Center, Kansas City, Kan.

The exhibit illustrates the autonomic nervous system. Various drugs such as atropine and epinephrine are listed and beside each name is a button. Upon pressing the button the electrical system is activated and appropriate lights show up on the panel indicating the site of action of the various drugs. Their site of action, whether they are preganglionic or postganglionic blocking or stimulating agents, is indicated.

Studies on Tetracycline Hydrochloride (Achromycin Hydrochloride)

JAMES RUEGSEGGER, S. M. HARDY, and RAYMOND W. CUNNINGHAM, Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y.

A new type of antibiotic, tetracycline hydrochloride, is presented that has markedly increased stability in solution and better tissue penetration, together with more rapid, higher, and longer lasting blood levels in much smaller doses when administered by either the oral or intravenous route.

New Diagnostic Methods for Moniliasis and Trichomoniasis

ALFRED B. KUPFERBERG, Ortho Research Foundation, Raritan, N. J., and WALTER J. NICKERSON, Rutgers University, New Brunswick, N. J.

These new diagnostic methods have been shown to be reliable yet are simple enough for handy office procedures. To demonstrate the diagnostic medium for Candida, photographs and actual cultures will be employed. The cultures on agar slants show strikingly that of all fungi only Candida species develop a dark brown to black pigment. Charts and photographs illustrate the selective nature of "Trichomonas Diluent," a solution which stains desquamated epithelial cells but leaves the trichomonad organism clear, since the living cell does not absorb the stain. This greatly facilitates and makes certain the diagnosis under the microscope.

Evaluation and Health Control of Older Persons

WILLIAM B. KOUNTZ, PHILIP G. ACKERMANN, TEOFIL KHEIM, and ALICE M. O'LEARY, Washington University School of Medicine and the St. Louis City Infirmary Hospital, St. Louis.

The exhibit is an evaluation of the clinical status of older and middle-aged persons. The studies show that there are inherent weaknesses of body function which are related in part to nutritional factors and the endocrine system. These changes suggest that a definite modification may be made in the course of diseases occurring in later periods of life such as arteriosclerosis, arthritis, diabetes, and heart disease.

Pancreatitis: Treatment Based Upon Pathogenesis

FRANKLIN B. MOOSNICK and JOHN B. FLOYD JR., Lexington, Ky.

The exhibit consists of panels (1) covering basic anatomy and physiology of the pancreas and pancreatic secretion, (2) dealing with pathogenesis with particular emphasis on disturbances in physiology which occur, and finally (3) dealing with the rational approach to therapy based on the concepts of pathogenesis that have been presented.

Clinical Application of Statistical Methods in Testing of Therapeutic Agents

LEO J. CASS, Brookline and WILLEM S. FREDERIK, Harvard School of Public Health, Boston.

A new application of the statistical method of the analysis of variances as applied to subjective observations. The mathematical representation is illustrated, and the method by which this technique is applied to an adequate clinical series and with completely unknown drugs is demonstrated. These include the advantages and weaknesses of the technique.

Food Allergy and Food Addiction

THERON G. RANDOLPH, Chicago.

Clinical differences in the type and timing of symptoms in food allergy, depending on the frequency of ingestion of specific allergens, are described. Although the occasional ingestion of an allergenic food is usually followed by the prompt development of an allergic reaction, an addictive type of response is apt to occur after its chronic cumulative use—resulting in an immediate improvement in symptoms followed by a delayed recurrence or hangover. This not only explains a patient's inability to suspect the existence of sensitivity to corn, wheat, milk, eggs, potatoes, coffee and other common foods, but also the compulsive craving for the immediate relatively beneficial effect following oft-repeated doses of such a food or its alcoholic extract, of importance, respectively, in the etiology of various clinical syndromes, including obesity and alcoholism.

Immunization in Poliomyelitis

HART E. VAN RIPER, National Foundation for Infantile Paralysis, New York.

The exhibit presents data on the properties of gamma globulin which produce temporary passive immunity, outlines the set-up of the field trials of gamma globulin, and presents the results of these trials.

Rehabilitation of Rheumatoid Arthritis

D. ELLIOTT O'REILLY and OTAKAR MACHEK, St. Louis University School of Medicine, St. Louis.

The exhibit of charts, pictures, and miniature models demonstrates a day of a rheumatoid arthritis patient, showing the problems he encounters, and the training, appliances, or gadgets that he can use to overcome these problems.

Phenylbutazone (Butazolidin)—A Non-Steroidal Agent for the Treatment of Rheumatic Diseases

BERNARD B. BRODIE, National Heart Institute, Bethesda, Md., EDWARD W. LOWMAN, JOHN J. BURNS, THEODORE CHENKIN, MURRAY WEINER, and J. MURRAY STEELE, New York University, New York.

The exhibit deals with the following aspects of phenylbutazone (Butazolidin) therapy: (1) therapeutic effects observed in a number of musculoskeletal disorders including rheumatoid arthritis, degenerative joint diseases (osteoarthritis), ankylosing spondylitis, gout, rheumatic fever, and peritonitis; (2) observations on absorption, excretion, tissue distribution, and biotransformation; (3) application of this information in the development of rational dosage regimens; (4) a comparison, with cortisone, of its anti-inflammatory activity and its effect on electrolyte and water balance, on ketosteroid excretion, and on eosinophil levels; and (5) observations of its toxic manifestations.

Prevention of Rheumatic Fever

MALCOLM J. FORD and JAMES WATT, Division of Chronic Disease and Tuberculosis, and the National Health Institute, U. S. Public Health Service, Washington, D. C., and JOHN P. HUBBARD and BURTIS BREESE, Council on Rheumatic Fever and Congenital Heart Disease, American Heart Association, New York.

The exhibit, which is based on the statement of the Council on Rheumatic Fever and Congenital Heart Disease of the American Heart Association, demonstrates the relationship between streptococcic infections and rheumatic fever, and emphasizes the fact that preventive measures are available that can prevent both the initial attack and recurrent attacks of the disease.

The Shoulder-Hand Syndrome: Clinical Features; Treatment with Sympathetic Block, Corticotropin and Cortisone

OTTO STEINBROCKER, DAVID NEUSTADT, and SAMUEL BOSCH, New York, H. HAROLD FRIEDMAN, Denver, and LYON LAPIN, Montreal, Canada.

This presentation consists of tabulations of the background, classification and etiologies of the condition, as accumulated so far by the authors, to bring out the clinical features and physiological characteristics of the symptom complex. It includes a summary of current therapy, together with a comparison of the author's results with sympathetic block, corticotropin, and cortisone. The clinical signs, injection technique, and results are illustrated by color photography.

Neurogenic Arthropathy and Dupuytren's Contracture

SEDGWICK MEAD, Washington University School of Medicine, St. Louis.

The exhibit consists of photographs of hands of patients with diseases of the nervous system having extremity deformities simulating various types of arthritis. Two types of Dupuytren's contracture are illustrated—one genetic and the other acquired. Relation to shoulder-hand syndrome and the arthritides is discussed. Case histories are given.

Ocular Prosthetics—Solutions of Several Common Fitting Problems

ALSON E. BRALEY, HOWARD WEBSTER, and LEE ALLEN, State University of Iowa, Iowa City.

Common plastic eye fitting problems have been analyzed and their solutions presented in graphic form. Oversized models demonstrate the basic engineering principles to be applied in shaping plastic eyes to achieve the best physiological and cosmetic results. A large collection of plastic eye forms cast directly from the original custom prostheses molds, as well as photographs of patients, illustrate the practical application of these solutions to the problems.

Office Procedures in Proctology

MANUEL G. SPIESMAN and LOUIS MALOW, Chicago Medical School, Chicago.

The common anorectal conditions are described, giving symptoms, diagnosis, and diagnostic aids. Office procedures and treatment are given in a concise manner. Drawings, sketches, and photographs, as well as brief descriptions, are utilized for a better understanding of proctologic problems. Anoscopy, proctoscopy, and sigmoidoscopy are described in a simple manner.

Medical Education

F. H. ARESTAD, E. H. LEVEROOS, EDWARD L. TURNER, and W. R. VON EHREN, Council on Medical Education and Hospitals, American Medical Association, Chicago.

The exhibit of the Council on Medical Education and Hospitals displays data on medical education, registration and approval of hospitals, training of interns and resident physicians, technical hospital personnel, and medical licensure. Data are included pertaining to lists of approved medical schools, hospitals approved for internships and residencies, and approved technical schools.

Studies of Analgesia in Human Beings

EDWIN G. GROSS, STUART C. CULLEN, and R. T. TIDRICK, State University of Iowa, Iowa City, Iowa.

The exhibit presents (1) an assay of analgesics in human volunteers, using the Hardy-Wolff-Goodell technique; (2) an assay of analgesics in the relief of postoperative pain and the pain of carcinoma; and (3) a comparison of morphine, meperidine (Demerol) and dl-dromoran hydrobromide given as intravenous supplementation during nitrous oxide anesthesia.

Blood Banks

W. G. RICE, St. Louis, American Association of Blood Banks.

The exhibit is designed to show the physician, technologist, nurse, and researcher as well as administrative personnel of hospitals and blood banks how a good blood bank can be set up, what it can accomplish, and how the association can be of assistance in the setting up and improvement of the blood bank activities. An outline of a national blood bank clearing house will be displayed also.

Voluntary Health Insurance

Howard Brower and Sidney Steck, Council on Medical Service, American Medical Association, Chicago.

The exhibit presents a graphic display of the types of voluntary health insurance plans available to the American people; the percentage of eligible persons enrolled in each state; and some of the characteristics of the voluntary plans, and progress being made in enrolling individuals, in increasing benefits, and broadening scope of coverage.

Transfusion of Platelet Concentrates

Allen H. Minor and Lee Burnett, Lenox Hill Hospital, New York.

The exhibit consists of pictorial representation of the preparation of platelet concentrates from normal blood and charts describing the clinical use of transfusions of these concentrates in the prophylaxis and control of thrombocytopenic bleeding.

Story of Pharmacy

Leroy A. Weidle, Jr., American College of Apothecaries, St. Louis.

The exhibit shows the story of pharmacy as well as the interprofessional relations between the medical and pharmaceutical professions.

The Medical Audit

W. A. Hutchison and H. A. Grimm, Grant Hospital, Chicago.

The exhibit of charts and photographs shows a system for reviewing the professional work in an average general hospital. The quality of professional work in the hospital is the responsibility of the medical staff. The purposes, method of organization, and benefits of the medical audit are stressed.

Blue Shield Medical Care Plans—The National Association of Blue Shield Plans

Frank E. Smith and Ned F. Parish, Blue Shield Medical Care Plans, Chicago.

The Blue Shield exhibit is designed as a service center where members of the American Medical Association and their guests are invited to stop for information about The Doctor's Own Plan.

The U. S. Navy Dental Corps Casualty Treatment Program

Comdr. J. V. Niiranen (DC) U. S. Navy, Naval Dental School, National Naval Medical Center, Bethesda, Md.

This exhibit illustrates various phases of the casualty treatment training program for naval dental officers. Featured in the exhibit are some of the training aids developed by the Navy dental school at Bethesda to develop skill and dexterity in treating casualties. One outstanding feature is a model of a military casualty fitted with several types of moulages simulating different injuries. The viewer is challenged to decide how he would handle the injuries. When the exhibit is displayed, the accepted type of emergency treatment is demonstrated at appropriate intervals. The aim of the exhibit is to create an interest in participating with Civil Defense authorities at the professional level demonstrated in the exhibit.

MOTION PICTURES

The following motion pictures will be shown daily in Kiel Auditorium from 12:15 p. m. to 2:45 p. m. in a room adjoining the Scientific Exhibit. The same program will be repeated each day for the benefit of physicians who may have conflicts in their schedules.

A Preliminary Demonstration of 3-D Cinefluorography

George H. Ramsey, Rochester, N. Y.

The introductory scene employs the thoracic portion of a prepared skeleton to illustrate the stereoscopic effect obtained by the method. A prepared skull introduces views of the living head and neck showing talking and swallowing. The passage of barium is shown through the thoracic portion of the esophagus. The film continues with views of the major thoracic structures (both superficial and internal) and concludes with scenes of a knee, a foot, and a hand. Sound, 17 minutes.

Congenital Malformations of the Heart, Part III, Cyanotic Congenital Heart Disease

Robert F. Rushmer, Seattle.

This film presents the embryology, origin, and the functional significance of congenital malformations of the heart which produce cyanosis. Sound, 30 minutes.

Fractures of the Humerus

Veterans Administration, Washington, D. C.

In this film, the anatomy of the bones and muscles with their pulls which cause displacements are demonstrated. In each fracture, the dangers of ill-advised manipulation are shown. Methods of reduction and maintenance of position are demonstrated, and the reasons for manipulations are brought into bold relief. Sound, 25 minutes.

Anti-Tuberculosis Drugs in the Medical and Surgical Treatment of Tuberculosis

H. Corwin Hinshaw, San Francisco.

This film shows what can be accomplished frequently for tuberculosis patients when hospital care, together with antibacterial drug therapy, pulmonary collapse, and surgical resection are all brought to bear upon the problem, when necessary. Sound, 30 minutes.

Special Evening Show

The following films will be shown Wednesday evening from 8:00 p. m. to 10:00 p. m. at the Statler Hotel. The Committee on Medical Motion Pictures has prepared the program.

Intra-Articular Injections of Hydrocortisone

William B. Rawls, New York.

This film shows the method of approach in order to inject joints of the fingers, toes, elbows, and shoulders, etc., with hydrocortisone. Sound, 29 minutes.

Principles of Fracture Reduction

Veterans Administration, Washington, D. C.

This film discusses certain principles, such as early reduction, neutralization of displacing muscle pulls, counter-traction, and suspension, and shows application of principles to reduction of fractures in a farmhouse situation where modern equipment is not available. Sound, 30 minutes.

Post Anesthesia Rooms

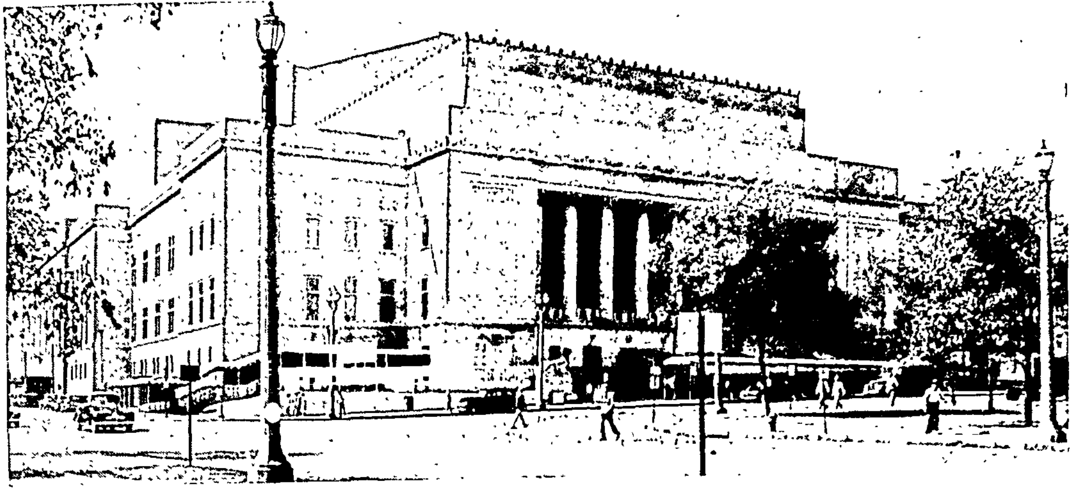
Scott M. Smith, Salt Lake City.

This film shows the various facilities of post anesthesia rooms of fifteen hospitals in the United States and Hawaii. Sound, 27 minutes.

Oral Cancer: Problem of Early Diagnosis

Charles S. Cameron, American Cancer Society, New York.

This film emphasizes techniques of biopsy in the diagnosis of cancer of the oral cavity. Complete mouth examinations as they should be carried out by physicians and dentists and a series of case histories are described. Sound, 25 minutes.



Kiel Auditorium

the TECHNICAL EXPOSITION

welcomes you

What are the new improvements in products and services? How do the technical advances serve general practice better? Your questions on these and other popular subjects will have ready answers in the 220 Technical Exhibits, occupying the Main Exhibition Hall of Kiel Auditorium.

Ever eager to show the profession what is new, after it has been proved of practical value, the exhibitors will bring to this Clinical Meeting their latest and finest offerings. From the pharmaceutical industry alone, more than fifty firms will present new remedies and new applications. Leading medical publishers will make it possible for you to examine almost any or all books of importance to the busy practitioner. Apparatus and instrument houses will have aisles of new and standard equipment.

Even more important than the bringing of these necessities and accessories of practice into one convenient exposition will be the assembly of representatives in charge of the exhibits. For the most part they will be researchers, technicians, factory engineers, or other qualified persons able to discuss the new applications, new methods and new techniques.

At this meeting, too, the Technical Exposition will have the happy advantage of being integrated with other convention activities—Scientific Exhibits, Motion Picture Program, Color Television Films, etc., all of which will be held in the spacious Kiel Auditorium. Open daily from 8:30 a.m. until 5:30 p.m., the exhibits will close at noon on Friday, December 4.

On this and the following pages, descriptive items from most of the exhibitors will give "previews" of the various booths. You are cordially invited to visit them all.

THOS. R. GARDINER
Business Manager and Director of Technical Exhibits

BOOKS

American Medical Association
Booth E-2

An invitation is extended to look over the display of A. M. A. publications for the medical profession and the general public. You probably read THE JOURNAL A. M. A. regularly, but here's an opportunity to examine copies of the nine *Special Journals*—to appraise their value in keeping you up to date. The display will also point out the advantages of membership in the A. M. A., and the attendant will supply further information on membership questions. Take a few minutes to register for a copy of TODAY'S HEALTH, the magazine for your reception room, and to leaf through the pamphlets of the Bureau of Health Education to become better acquainted with the wide variety of authoritative health information available to your patients and the general public.

The Blakiston Company
Booth A-8

The Blakiston booth will comprise their latest titles, including the just published new editions of these distinguished works: Elwyn's *Diseases of the Retina*, 2nd edition; Patten's *Human Embryology*, 2nd edition; Morris' *Human Anatomy*, 11th edition; Nelsen's *Comparative Embryology of the Vertebrates;* Harbaugh and Goodrich's *Fundamentals of Biology;* and Rusk and Taylor's *Living with a Disability*. Page proofs of the new 2nd edition of Lillie's *Histopathologic Technic* will also be available for your examination.

Chicago Reference Book Company
Booth D-28

Webster's *New International Dictionary*, Second Edition, with Reference History contains 605,000 entries, covering all fields. Actually, it is a compilation of many specialized dictionaries under one cover, such as Law, Medicine, Surgery, Horology, Engineering, Heraldry, etc. In type matter it equals a 20-volume encyclopedia, giving authoritative and concise answers to questions on any subject. This outstanding reference work is available now in 3-volume and 5-volume styles and also in India paper.

F. A. Davis Company
Booth E-9

Highlighting the F. A. Davis 75th Anniversary exhibit is the New Looseleaf *Cyclopedia of Medicine, Surgery, Specialties.* Among a complete display of titles, the latest, Ficarra *Emergency Surgery* will attract your special attention.

Encyclopaedia Britannica, Inc.
Booth E-21

Encyclopaedia Britannica, Inc., announces with a great deal of pride the release of the 1953 edition—complete with new population figures, based on the latest governmental census, together with many new illustrations and completely new articles of special current interest. It is the biggest revision of *Encyclopaedia Britannica* in over 25 years. At the booth, visitors may participate in a generous new Britannica program and inspect several bindings with Year Book and descriptive research material.

Encyclopedia Americana
Booth F-21

Here, doctors and their guests may examine the new 1953 Edition of *Encyclopedia Americana.* In addition to this well known reference, Americana will also exhibit the Fortieth Anniversary Edition of the *Book of Knowledge,* a "standby" in children's reference works.

Grune & Stratton
Booth E-13

Grune & Stratton representatives will be happy to see you again and to show you some of their latest titles. Included in the display will be: *Roentgen Diagnosis of the Heart and Great Vessels* (Zdansky and Boyd); *Stress Incontinence in the Female* (Ullery); *Multiple Myeloma* (Snapper et al.); *Diseases of the Liver* (Spellberg); *Rh-Hr Blood Types, Applications in Clinical and Legal Medicine and Anthropology* (Wiener); and many other important books in every phase of medicine and surgery.

Paul B. Hoeber, Inc.
Booth A-6

Every Hoeber-Harper book in print will be on the shelves at booth A-6, where you are welcome to browse at your leisure. Unusual new books of special interest to practitioners include: Smith & Wermer's *Modern Treatment;* Kyser's *Therapeutics in Internal Medicine* (2nd Edition); Stewart's *Cardiac Therapy;* and Cantor's *Ambulatory Proctology.*

Lea & Febiger
Booth A-9

Be sure to see the many new 1953 books and new editions published by Lea & Febiger: Bonica, *The Management of Pain;* Herbut, *Gynecological and Obstetrical Pathology;* Bellet, *Clinical Disorders of the Heart Beat;* Schroeder, *Hypertensive Diseases;* Burch, Abildskov and Cronvich, *Spatial Vectorcardiography;* Goldberger, *Unipolar Lead Electrocardiography and Vectorcardiography;* Hollander, *Comroe's Arthritis and Allied Conditions;* Portis, *Diseases of the Digestive System;* Lichtman, *Diseases of the Liver, Gallbladder and Bile Ducts;* Cozen, *Office Orthopedics;* Boyd, *Textbook of Pathology;* Epstein and Davidoff, *Atlas of Skull Roentgenograms;* and many others.

J. B. Lippincott Company
Booth A-2

J. B. Lippincott Company presents for your approval a display of professional books and journals geared to the latest and most important trends in current medicine and surgery. These publications, written and edited by men active in clinical fields and teaching, are a continuation of more than 100 years of traditionally significant publishing.

The Macmillan Company
Booth A-16

Since the A. M. A. Meeting in New York last June, The Macmillan Company has scheduled for publication many new and timely medical books. Among those which will be ready for exhibit at this Clinical Meeting will be Parsons-Duke-Elder, *Diseases of the Eye* (12th edition); Lucas, *The Symptoms and Treatment of Acute Poisoning;* and Anderson and Arnstein's *Communicable Disease Control* (3rd edition). The latter will be offered as a valuable addition to your library.

The C. V. Mosby Company
Booth C-7

A wealth of new information will be available at the C. V. Mosby booth, where you are invited to browse at your convenience. Among some of the recent titles are: Crossen *"Diseases of Women";* Anderson, *"Pathology";* Lewis, *"Pathology of Tumors";* Horsley and Bigger, *"Operative Surgery";* Jensen, *"Modern Concepts in Modern Medicine";* and many others.

Philosophical Library
Booth F-10

The Philosophical Library will exhibit some of its most recent publications, such as *Essays in Science* by Albert Einstein; *Nuclear Physics* by Werner Heisenberg; *Science and Man's Behaviour* by Trignant Burrow; and *Music Therapy* by Edward Podolsky.

W. F. Prior Company, Inc.
Booth F-6

At booth F-6 the W. F. Prior Company will display its famous loose-leaf references: Tice's *Practice of Medicine;* Lewis' *Practice of Surgery;* Brennemann's *Practice of Pediatrics;* and Davis' *Gynecology and Obstetrics.* A visit here will demonstrate to visitors what epochal changes have occurred in medicine during the past few years.

W. B. Saunders Company
Booth A-1

Saunders standards—such as Cecil-Loeb's *Medicine,* Mitchell-Nelson's *Pediatrics, Current Therapy, Dorland's Dictionary, Medical and Surgical Clinics of North America*—and a fine line of new books will make booth A-1 well worth repeated visits. Some titles of special interest are: Gross' *Surgery of Infancy and Childhood;* Cattell & Warren's *Surgery of the Pancreas;* Dunphy & Botsford's *Physical Examination of the Surgical Patient;* Sheldon, Lovell & Mathews' *Clinical Allergy;* Lewis' *Practical Dermatology;* and Parsons & Ulfelder's *Atlas of Pelvic Operations.* To their Medical and Surgical Clinic line Saunders are adding *The Pediatric Clinics of North America,* the first issue to be published in February, 1954.

State Journal Advertising Bureau
Booth A-18

The 34 state medical journals, which comprise the State Journal Group, have the same advertising standards as publications of the American Medical Association. With a total circulation of 137,046, the journals represent 39 state medical societies. Prospective advertisers are invited to stop at the S. J. A. B. booth to secure sample journals and the current rate schedule. Copies of the recent editorial survey will also be available.

DIAGNOSTIC DEVICES

Ames Company, Inc.
Booth A-4

Ictotest, a new 30-second simple tablet test for urine bilirubin will be featured here as an aid to diagnosis and management of jaundice and hepatitis. Other Ames diagnostic tablet tests on exhibit include: Clinitest, Bumintest, Acetest, and Hematest—for the determination of urine-sugar, albumin, acetone, and occult blood.

Beck-Lee Corporation
Booth C-18

Trained technicians will be on hand in booth C-18 to demonstrate and discuss Beck-Lee's latest and finest electrocardiographs, including their portable direct-writing Cardi-All. This instrument offers many unique features, such as the compamatic circuit, automatic stylus protection, and patient cable fused leads. Models E and ERA Quartz String Galvanometer-type electrocardiographs will also be on display.

Edin Company, Inc.
Booth F-2

Edin's latest model direct writing electrocardiograph will be of special interest in booth F-2. This fine instrument reflects the wide experience gained by the Edin Company in manufacturing electrocardiographs, electroencephalographs, amplifiers, recorders and other electronic instruments for clinical and research applications. Representatives will welcome an opportunity to discuss your requirements with you.

Jones Metabolism Equipment Co.
Booth D-16

Technicians and representatives in booth D-16 will be pleased to demonstrate the Jones Metabolism equipment. A visit here will demonstrate how the routine use of the BMR can be of great help in many seldom-thought-of phases of practice.

Sanborn Company
Booth C-9

Latest Sanborn instruments for clinical diagnosis, shown in booth C-9, will include: the Viso-Cardiette, direct-writing electrocardiograph; the Metabulator, self-enclosed metabolism tester; and the new Sanborn Twin-Beam, two-channel photographic recorder, for simultaneous (or separate) recording of diagnostic phonocardiograms and high-deflection speed electrocardiograms, plus electrical auscultation. Complete data will also be available on the Sanborn Twin and Poly-Visos, two and four-channel biophysical research recording systems; and on the Sanborn Electromanometer, widely-used instrument for physiologic pressure measurements.

DIETETIC PRODUCTS

Adolph's, Ltd.
Booth E-18

The internationally-known Adolph's Meat Tenderizers (seasoned and non-seasoned) which make meat more tender; and Adolph's Salt Substitute, their newest aid to the low-sodium dieter, will merit your attention at booth E-18. Samples and information on both products will be available.

American Bakers Association
Booth C-14

Enriched Bread, now fully 80 per cent of marketed white bread, has resulted from a program initiated by physicians some 17 years ago in the aim to overcome widespread and serious deficiencies of B vitamins and iron in the American dietary. The exhibit of the American Bakers Association defines the nutritional value of enriched bread and its place in the diet. An interesting leaflet on enriched bread in normal and special diets is available.

The Best Foods, Inc.

Booth D-12

"Interesting . . . good" is what you will say after a visit to the Best Foods booth. Here you will see Hellmann's and Best Foods Real Mayonnaise, French Dressing, Old Homestead French Dressing, Relish Sandwich Spread, Best Foods Mustard with Horseradish and Fanning's Bread & Butter Pickles. You may also learn more about Nucoa Margarine, the first yellow margarine with food value in every single ingredient. No benzoate preservative and no synthetic flavor are added. Even Nucoa's sunny color comes from nature. Its vitamin A is carotene; its vitamin D is pure calciferol. Miss Elsie Stark, Director of Consumer Education, will welcome you at the booth and provide information on the properties and uses of Hellmann's and Best Foods Products.

The Bib Corporation

Booth E-33

The Bib Corporation will exhibit an exact scale model of their canning plant. This model which contains over 1,000 working parts required two months of labor to assemble. At the exhibit visitors will be given a taste test of Bib Orange, Orange-Apricot and Prune-Orange juices. Doctors registering at the booth will receive descriptive and informative literature on all three Bib Baby Juice flavors.

Borcherdt Malt Extract Company

Booth D-26

Like a "malted"? Stop at the Borcherdt booth and taste Malt Soup Extract in milk. It's delicious. This dependable laxative modifier of milk for constipated babies has also proved effective in softening the hard dry stools of constipated elderly patients. Taste it and see why baby and grandma both like it.

Carnation Company

Booth C-10

A cordial reception awaits you at booth C-10 where you will see a series of translites on Carnation's canning and sterilization process. Medical representatives will explain the processing and give you reasons why Carnation Milk deserves consideration as a first choice in infant feeding formulas.

The Coca-Cola Company

Booth C-21

Ice cold Coca-Cola will be served through the courtesy and cooperation of the Coca-Cola Bottling Company of St. Louis and The Coca-Cola Company.

General Foods Corporation

Booth E-10, F-8

For your enjoyment, stop at booth F-8 for a refreshing beverage—Bird's Eye Orange Juice, made of the quick frozen concentrate; or Instant Sanka, 97% caffein free. Minute Rice and Minute Tapioca will also merit your attention here. Wives will be most welcome and may want to register for a special assortment of recipes. At booth E-10, delicious Postum Milkshakes will be served. Postum, a favorite beverage for many years, will be featured as a refreshing milk shake and as a nightcap. While at this booth, ask about D-Zerta, a saccharine-sweetened fruit-flavored gelatin especially suitable for diabetic and reducing diets. Literature on all products will be available at both exhibits.

Gerber's Baby Foods

Booth B-3

Gerber's will exhibit their wide variety of starting Cereals, Meats for Babies, Strained Foods and Junior Foods which provide for complete first-year supplementary feeding. A visit to the Gerber booth will help you keep in touch with "What's new in baby foods." It will permit you to review revised and new service literature on infant care and adult therapeutic and convalescent diets.

"Junket" Brand Foods

Booth B-18

Essential facts on the chemistry of the rennet enzyme and the nutritional significance and psychologic value of rennet desserts in the diet of infants and children will be discussed. The enzymatic action of rennet in producing softer, finer, more readily-digestible milk curds will be illustrated by enlarged photos. Literature describing the dietary applications of rennet products will be available for your reference.

Loma Linda Food Company

Booth D-13

As an aid in solving many feeding problems, especially those related to allergy, the new Soyalac Infant Food will be of particular interest. Attendants at the booth will be happy to discuss the uses of this hypo-allergenic food in infant, child and adult special diets. A sample of flavorful Soyalac will be served at the exhibit.

M & R Laboratories

Booth C-2

Similac representatives are happy to take part in this meeting and to have an opportunity to discuss with you the role of Similac in infant feeding. At the booth they will have the latest pediatric research conference reports and current reprints of pediatric nutritional interest.

Mead Johnson & Company

Booth D-18

Featured products in the Mead Johnson exhibit will be: Lactum, Mead's liquid formula for infants; Dextri-Maltose, a carbohydrate of choice in infant feeding; vitamins and cereals for infants and children; Sustagen, a new product offering a completely new approach to tube feeding; and Levugen, the first pure fructose for intravenous infusion.

Pepsi-Cola Company

Booth F-22

Pepsi-Cola Company will play "host" to members of the American Medical Association at this clinical meeting. Ice-cold Pepsi will be "at home" in booth F-22. Plan to drop in and say "hello."

Pet Milk Company

Booth C-20

Specially trained representatives will be in attendance to discuss the merits of Pet Evaporated Milk in infant feeding and Pet Nonfat Dry Milk in high protein diets. A variety of time-savers for busy physicians will be furnished on request. Miniature Pet Milk cans will be given to visitors at the exhibit.

Ralston Purina Company

Booth C-6

The Ralston Purina Company's free dietary services may be examined and ordered at booth C-6. These include a series of Low Calorie diets; five different food Allergy diets; a diet for nomal Pregnancy; a set of Feeding Direction Forms for infants and young children; and Normal and Gaining diets. Professional personnel will be available to answer your questions about Ry-Krisp and Ralston Whole Wheat Cereals.

The Seven-Up Company

Booth E-6

"Fresh Up with 7-Up" is your invitation to visit booth E-6 for a chilled bottle of this sparkling drink. Representatives at the exhibit will be happy to serve you.

Swift & Company

Booth B-6

Strained Egg Yolks for Babies is the featured attraction at the Swift exhibit. This new product, by the originator of 100% Meats for Babies, provides a convenient, economical way to feed egg yolks. Swift representatives will be glad to sample and discuss this new product with you. Also available will be information on many clinical studies which have been sponsored by Swift & Company on the value of meat in the infant diet.

Sunkist Growers

Booth A-5

Two widely separated applications of citrus fruits to therapy will be subjects of the Sunkist Growers' exhibit. One deals with the use of lemon juice in increasing palatability of low sodium diets and the other with the contribution of the protopectins found in oranges to intestinal function. The analogy between the role of the pectins in the economy of the plant and their physiological value to the human is graphically portrayed.

OFFICE EQUIPMENT & FURNITURE

A. S. Aloe Company

Booth D-17

A. S. Aloe will feature Desert Sand Steeline, a new custom blond grain finish created especially to combine the rugged durability of steel with the warm elegance of fine wood. Presented also will be the new Aloe Compax X-Ray, engineered to grow with your practice. Starting with a 20 MA portable, it builds to a complete 50-90 installation in a few economical steps. See both at booth D-17.

W. D. Allison Company

Booth B-19

Physicians' and surgeons' examining room furniture keynote booth B-19. The New Allison Fleetwood Suite, completely new and modern in basic design and improved mechanical features, is presented. Some of the new features include a recessed front, pedestal design "push button" stirrups that store out of the way—and finishes that will blend or match any decoration.

Burroughs Adding Machine Company

Booth B-23

Burroughs Corporation will exhibit a newly developed style of the Sensimatic Accounting Machine with description features designed specifically for use in a doctor's office. Continuous demonstrations will show how error-proof statements may be prepared rapidly and neatly—ready for mailing by the first of the month with all accounting records completed. Other Burroughs accounting equipment will show how savings in time, effort and costs may be attained in handling figuring work.

Burton Manufacturing Company

Booth D-22

If you have a lighting problem, you won't want to miss the Burton exhibit in booth D-22. Prominent among the many features are two new additions to the Super Power light line: the Super Power Jr., a featherweight floor stand model; and the new Super Power Sr. with the big, king-size reflector for clinics, hospitals or office surgery. Other attractions include a new microscope illuminator slide, Pipette dryer unit, and the new 1953 Uvilux Black Light (Woods Light)—sealed beam 100 watt model.

Wilmot Castle Company

Booth E-11

The Castle exhibit will feature an all-purpose autoclave, the Speed-Clave. Because it provides steam-pressure sterilization, this fast-acting autoclave helps prevent cross-infection with the virus of infectious hepatitis. The Speed-Clave attains operating temperature in eight minutes from a cold start, or four minutes from a hot start. Castle Operating Lights will also be shown.

Gray Manufacturing Company
Booth D-27

Gray Manufacturing Company, originators of the telephone pay station in 1891, will emphasize their newest line of clinical and office dictation equipment, including the complete line of Gray Audograph individual recording and transcribing equipment and the Gray PhonAudograph, for centralizing the transcribing of written communications. Designed to save time for busy doctors and hospital personnel, the Gray systems can be tailor-made to suit individual requirements.

Miles Reproducer Co., Inc.
Booth F-4

Case histories, lectures and dictation may now be recorded at a 60 foot radius with Walkie-Recordall—an 8-lb., self-powered battery-recorder-transcriber. It operates in or out of the closed briefcase, indoors or outdoors, while stationary, walking, riding or flying. The Voice-Activated "Self-Start-Stop" feature automatically starts and stops the recording from microphone or telephone, thus eliminating supervision and the recording of silent periods. While facilities for transcribing are available, transcription may be eliminated due to ease of handling identifiable, compact, indexed recordings without the delay of rewinding. Up to 8 hours of permanent recordings may be accumulated at intervals on an "endless" belt costing 25 cents.

Ritter Company, Inc.
Booth E-7

Of special interest here is a demonstration of Ritter's new "Multi-Level" Tables with motor hydraulic elevation. Other attractions include a universal examination and treatment table for general practice; a table designed specifically for proctology; and an Underwriter-approved, explosion-proof, medium surgery table with unique side rail attachments. Ritter tables can be "tailor made" to suit the needs of most specialties.

Shampaine Company
Booth B-21

The Shampaine Company will feature an outstanding new line of physicians' examining-room furniture, "Steelux with I.D." "I.D." stands for Integrated Design, meaning that the furniture is as compact and efficient as modern manufacture can achieve. The display will have both color and movement. The Shampaine Color Co-Ordinator provides a colorful background, and the examining-table's many automatic and mechanical features invite audience participation. Two popular Specialists' Chairs will also be shown.

PERSONNEL BUREAUS

Continental Medical Bureau
Booth A-22

Continental Medical Bureau, agency specializing in California and the Rocky Mountain area will be in booth A-22. Doctors from this area interested in staff personnel are invited to drop by and review brochures of men who are available. Physicians and surgeons interested in "going west" will also find up-to-date information on available appointments.

The Medical Bureau
Booth A-7

Burneice Larson offers the facilities of The Medical Bureau, an organization serving as counselors in problems of medical and hospital personnel. Recommendations can be made of Diplomates of the American Boards qualified to head their departments, physicians interested in assistantships or further training, general practitioners and industrial physicians, administrators, public health specialists, executive and supervising nurses, scientists, technologists, dietitians, social workers and other professional personnel. Burneice Larson will be in charge of the exhibit.

Woodward Medical Personnel Bureau
Booth C-22

To those doctors seeking to re-locate or who wish to reorganize or augment present staffs, Ann Woodward offers the facilities of the Woodward Medical Personnel Bureau. The details of excellent opportunities for above-average income with good security and fine future potential may be investigated. You may also review the records of some exceptionally well-qualified younger doctors just finishing their formal training as well as diplomates of the specialties qualified to head departments. The complete files for these purposes may be found at booth C-22 where Mrs. Woodward will be available to greet and assist you.

PHARMACEUTICALS

Abbott Laboratories
Booths C-1, 3, 5

To demonstrate Sucaryl, a stable non-caloric sweetener, Abbott will serve coffee and Sucaryl-sweetened cookies. Sucaryl which has no bitter aftertaste permits the patient on a diabetic or weight-reducing diet to enjoy sweetness in cooked, baked, canned and frozen foods. Abbott also will exhibit three other products: Erythrocin, a selective antibiotic of choice against staphylococci, streptococci and pneumococci; Blutene, a new orally-effective agent for treatment and prevention of abnormal uterine bleeding of functional origin; and Selsun, an easy-to-apply liquid preparation for treatment of seborrheic dermatitis of the scalp.

American Hospital Supply Corporation
Booth E-23

Prominent in the American Hospital Supply exhibit will be Travert, Baxter Invert Sugar Solutions for parenteral carbohydrate, giving twice as many calories in the same infusion time; and the new Plexitron Blood Pump, for rapid pressure transfusions with expendable equipment. On display also will be the Anatomical Models, made of life-like flexible plastic; the Venipuncture Training Arm; Dade Blood Typing Serums; Sylvana Serology Antigens; and other laboratory specialties.

The Armour Laboratories
Booth A-24

Acthar, Armour's brand of Adrenocorticotropic Hormone (Corticotropin—ACTH) and its many Council-accepted indications are presented in booth A-24. Representatives will be glad to discuss with you other Armour products, such as Adrenal Cortex Extract, Posterior Pituitary Liquid and Thyroid.

Ayerst, McKenna & Harrison, Ltd.
Booth D-19

Ayerst, McKenna & Harrison take pleasure in extending a cordial invitation to all physicians attending this meeting to visit booth D-19. Literature and information relative to Premarin and Antabuse will be available. Medical representatives will be glad to discuss these and other new developments with you, answer your questions, or just have you relax at the booth.

Bilhuber-Knoll Corp.
Booth E-19

For information on the latest advances in the use of Metrazol therapy, visit the Bilhuber-Knoll exhibit, booth E-19. Your discussion of these recent developments will be welcomed. Information concerning other Bilhuber medicinal chemicals, such as Theocalcin, Dilaudid, and Bromural, will also be available. Representatives will be pleased to discuss these prescription chemicals with you.

George A. Breon & Company
Booth A-19

Lanteen Medical Laboratories, Inc., extends a cordial invitation to visit booth A-19. Representatives will be on hand to discuss these well known gynecic specialties.

Burroughs Wellcome & Co. (U.S.A.) Inc.
Booth E-32

The Burroughs Wellcome exhibit will feature the following products: Aerosporin Sulfate, an antibiotic bactericidal to many gram-negative bacilli, including pseudomonas aeruginosa (B. pyocyaneus); Hexameton Chloride, an autonomic ganglion blocking agent for treatment of hypertension; Digoxin, a pure, rapidly eliminated, crystalline glycoside; intermediate acting Globin Insulin, a clear solution requiring no shaking; and Anectine Chloride brand Succinylcholine Chloride, a short acting skeletal muscle relaxant which permits minute-to-minute control for long or short surgical procedures.

The Central Pharmacal Company
Booth D-25

Interest at the Central Pharmacal exhibit will center on the three dosage forms of Trisulfazine—Palatabs, Suspension and Tablets. The Trisulfazine products represent specialties "born of Central's original research" and were among the first ones to be accepted by the Council.

Chilean Iodine Educational Bureau, Inc.
Booth D-7

The Chilean Iodine Educational booth, D-7, points out the values of iodine and its compounds and preparations in the fields of medicine, surgery, nutrition and sanitation. Samples of official and Council-accepted drugs containing iodine will be displayed. Reprints of various papers and other facilities of the Bureau will be offered at the exhibit.

Church & Dwight Co., Inc.
Booth B-15

In booth B-15, Church & Dwight Co., Inc., will exhibit its well known Bicarbonate of Soda, Arm & Hammer and Cow Brands. While these brands of U. S. P. quality are used extensively in medical practice, this year's Clinical exhibit will emphasize their value in cleaning the teeth. For this purpose, they are acceptable to the Council on Dental Therapeutics of the Ameriman Dental Association. Colorful Dental Health booklets and handy pocket-sized samples suitable for traveling may be had at the booth.

Ciba Pharmaceutical Products, Inc.
Booth E-26

Ciba in booth E-26 will feature an interesting animated exhibit, using carved plastic coordinated with sound to illustrate the mechanism of maintaining both normal and pathological phases of blood pressure. The effects of neurogenic and humoral substances elaborated by the brain and kidney will be demonstrated and the influence of pheochromocytoma on blood pressure, diagnosis and treatment will be shown. The role of Regitine, Apresoline and Esomid, successfully used in the diagnosis and treatment of hypertension, will be emphasized.

Doak Pharmacal Co., Inc.
Booth A-20

Doak Pharmacal Co., Inc., pioneers in dermatological products for over a quarter century, will feature two specialties: Tersus, an original soapless detergent for skin and scalp, particularly useful in oily conditions; and Salinidol, containing 5% Salicylanilide N.F. in a greaseless base, indicated in the treatment of tinea capitis.

Durex Products, Incorporated
Booth F-1

Durex Products will show a large variety of vaginal diaphragms and cervical occlusive devices. These will include the Coil Spring, Mensinga, Dumas, Bowbend (which requires no inserter), Duraflex (matrisalus type), the Flat Rim, Mizpah and Aluminum Cervical Caps. A Sponge Rubber Teaching Model, to demonstrate diaphragm placement; and Sets packaged in plastic containers, comprising a diaphragm and tubes of Lactikol Jelly and Creme and an Inserter, will also be shown.

Eaton Laboratories, Inc.
Booth B-4

Latest clinical findings on Furadantin N.N.R. will be shown at the Eaton booth. This new antibacterial nitrofuran is producing excellent results in refractory infections of the urinary tract. Chemically related to Furacin, it is the first of the family of nitrofurans to be made available for systemic administration. Included among its advantages are absence of crystalluria, abdominal distress and pruritus. Other Council-accepted products on display will include various dosage forms of Furacin and Lorophyn.

Fellows Medical Mfg. Co., Inc.
Booth D-2

Chloral Hydrate, a relatively safe, time-tested sedative is shown in convenient capsule form. Fellows have successfully encapsulated chloral hydrate (in two strengths), permitting the effective use of this important drug for day-time sedation and hypnosis. Fellows Chloral Hydrate Capsules (7½ grains) produce a normal type of sleep usually without depressant after-effects. Representatives at the booth will be pleased to discuss this important addition to the field of sedative and hypnotic therapy.

Geigy Pharmaceuticals
Booth B-22

Tromexan, an oral anticoagulant noted for its fast action and added safety factor in the treatment of thromboembolic disorders, is a featured attraction at the Geigy exhibit. Representatives at the booth will welcome your questions about this and other therapeutic developments.

The Harrower Laboratory Inc.
Booth A-17

The display of the Harrower Laboratory, Inc., will be devoted to Mucotin, available in tablet or liquid form for peptic ulcer therapy. Mucotin combines the protective coating characteristics of gastric mucin with the antacid properties of aluminum hydroxide and magnesium trisilicate. A feature of the Mucotin exhibit is a giant size model of a gastroscope in position for observation of a gastric ulcer.

Holland-Rantos Company, Inc.
Booth E-1

Physicians interested in medical contraception are invited to inspect the complete H-R line of ethical contraceptive specialties in booth E-1: Koromex diaphragms (standard coil spring, Mensinga, Matrisalus, and cervical caps); Koromex Jelly and Cream; and Sets. Holland-Rantos representatives will be pleased to have you register for their latest literature.

Lederle Laboratories Division
Booth B-2

You are cordially invited to visit booth B-2 where you will find representatives prepared to give you the latest information on Lederle products.

Eli Lilly and Company
Booths B-10, 12

Antibiotics, cardiac drugs, decongestants, antihistamines, antithyroid drugs, and aids for the diabetic are featured in the Lilly display. Lilly salesmen will welcome your questions about these and other recent therapeutic developments.

Mallinckrodt Chemical Works
Booth E-12

Representatives in attendance at the Mallinckrodt exhibit will welcome an opportunity to discuss the products on display, or any Council-accepted chemical manufactured by the company.

McNeil Laboratories, Inc.
Booth C-17

McNeil Laboratories extends a cordial invitation to members of the American Medical Association to visit booth C-17. On display will be Butisol Sodium, an "intermediate" sedative; Syndrox Hydrochloride; and other Council-accepted products.

Merck & Co., Inc.
Booth C-13

Hydrocortone and Cortone will be featured in the Merck booth. Conditions in which these products have proven of service include: rheumatoid arthritis; intractable bronchial asthma; acute rheumatic fever; inflammatory eye diseases; and many dermatologic conditions, both allergic and non-allergic. Hydrocortone Acetate is of particular value in relieving the pain and stiffness of individual rheumatoid and osteoarthritic joints when given by intra-articular injection. Other featured products are: Mephyton, an antidote to certain anticoagulant-induced hypothrombinemia; and Nalline, the first specific narcotic antidote.

The Wm. S. Merrell Company
Booth A-3

Tace, a new drug for the hormonal containment of prostatic carcinoma, highlights the Merrell exhibit. Tace (chlorotrianisene) possesses certain peculiar attributes not common to other estrogens. In the dosages used in experimental studies, it apparently induced less pituitary or adrenal hyperplasia than other estrogens. This one fact—lack of apparent effect upon the pituitary-adrenal—has caused considerable interest among urologists treating carcinoma of the prostate with estrogens.

Monsanto Chemical Company
Booth B-13

The Monsanto exhibit will feature the use of saccharin, a powerful non-nutritive sweetener manufactured by the company for diabetics and others on sugar-free diets. Monsanto's popular saccharin booklet, containing 70 recipes, ranging from salad dressings to cakes, will be offered at the booth.

Nepera Chemical Co., Inc.
Booth E-16

Mandelamine, a urinary antiseptic, and Neohetramine, a highly effective antihistamine, will merit your attention in booth E-16. The bacteriostatic and bactericidal action of Mandelamine in urinary tract infections is of approximately the same order as the sulfonamide drugs or streptomycin. Mandelamine rarely causes side effects. Because of Neohetramine's exceptional tolerance and virtual lack of sedation, it has a wide range of therapeutic dosage.

Organon, Inc.
Booth E-17

Organon will feature the outstanding pharmaceutical development of Bifacton—Vitamin B_{12} with intrinsic factor concentrate. Bifacton represents the most highly purified and potent oral anti-pernicious-anemia preparation available to the medical profession. In Bifacton, the elusive intrinsic factor has been captured in remarkably concentrated form and combined and bound with vitamin B_{12}. The Bifacton story is one which will interest all physicians who employ oral vitamin B_{12} therapy. Visit the Organon booth for an interesting and timely display.

Ortho Pharmaceutical Corporation
Booths D-21, F-19

The physician's responsibility in marriage counseling is the theme of one of Ortho's exhibits. This dramatic and provocative subject should be of interest to physicians. Ortho's other exhibit will be concerned with diagnostic products, such as Rh-Hr anti-sera, which have been received by many laboratories and blood banks.

Parke, Davis & Company
Booth A-13

A cordial welcome awaits you at the Parke-Davis booth. Members of the P-D medical service staff will be on hand to greet you and to discuss their well-known specialties.

Chas. Pfizer & Co., Inc.
Booth C-11

Well-informed representatives in booth C-11 will be happy to supply you with information and answer your questions on Pfizer products. The newest dosage forms of Terramycin will be the featured attractions.

Pharmacia Laboratories, Inc.
Booth F-13

Pharmacia Laboratories, Inc., will show its Council-accepted product, Azulfidine, a new sulfa drug for the treatment of ulcerative colitis. Azulfidine is an Azo compound of salicylic acid and sulfapyridine. Literature and reprints of outstanding papers may be had upon request.

Riker Laboratories, Inc.
Booth E-28

Riker Laboratories, Inc., presents Veriloid (Brand of Alkavervir) Intramuscular and Intravenous Solutions. Veriloid, a powerful hypotensive agent, provides means of reducing the blood pressure in a matter of minutes. Its influence is positive, dependable and profound. It is indicated whenever the symptoms of hypertension must be controlled rapidly, as in hypertensive crisis, malignant hypertension, toxemia of pregnancy, pre-eclampsia and eclampsia. Veriloid solutions reduce blood pressure by central action.

A. H. Robins Company, Inc.
Booth C-4

The A. H. Robins exhibit features Robalate, N.N.R., antacid-demulcent, indicated in peptic ulcer therapy and hyperacidity. The pharmaceutically elegant tablets, each containing 0.5 gm. dihydroxy aluminum aminoacetate, are notable for exceptional palatability.

Rystan Company, Inc.
Booth E-15

Rystan features Council-accepted Chloresium Ointment and Chloresium Solution (Plain), containing purified, non-toxic water-soluble derivatives of chlorophyll. In the topical treatment of wounds, burns, ulcers and dermatoses, these therapeutic chlorophyll preparations promote the normal growth of healthy granulation tissue, relieve itching and irritation, and deodorize malodorous lesions. Reprints of published clinical and laboratory studies on Chloresium therapy are available; and representatives will be pleased to discuss specific applications of these preparations.

Sandoz Pharmaceuticals
Booth E-31

With pleasure and pride, Sandoz Pharmaceuticals invite you to visit their scientific type exhibit in booth E-31. Representatives will be pleased to welcome you.

Schering Corporation
Booth D-1

Members of the American Medical Association and their guests are cordially invited to visit the Schering exhibit where new therapeutic developments will be featured. Schering representatives will be present to welcome you and to discuss with you these products of their manufacture.

Julius Schmid, Inc.
Booth D-6

Julius Schmid, Inc. have prepared an interesting and informative exhibit on their products—Ramses Flexible Cushioned Diaphragm, Ramses Vaginal Jelly and other Ramses Gynecological products, all of which enjoy A. M. A. Council acceptance. Introduced to the medical profession more than three decades ago, the Ramses line today is better than ever because of the firm's continuous research and improvement.

G. D. Searle & Co.
Booth B-14

You are cordially invited to visit booth B-14 where members of Searle's medical and medical service departments will be happy to answer your questions regarding Searle Products of Research. Especially presented will be new uses for Dramamine and Banthine. Other featured items will include Searle Aminophyllin, Alidase, Metamucil, and Diodoquin.

Sharp & Dohme, Inc.
Booth E-8

Research data relative to oral penicillin therapy is featured by Sharp & Dohme, Division of Merck & Co., Inc. The exhibit endeavors to justify reliance on oral penicillin for the therapy of the majority of penicillin treatable infections, excluding fulminating diseases requiring hospitalization. Expertly trained personnel will be present to discuss these observations.

Smith, Kline & French Laboratories
Booth D-20

You are cordially invited to visit the SKF booth, D-20. Specially trained representatives will be pleased to tell you about their Council-accepted and exempted products and to answer any questions you may have concerning the possible use of these items in your practice.

E. R. Squibb & Sons
Booths E-25, 27, 29

New information on Squibb Products and new brochures useful to the general practitioner will be presented at booths E-25, E-27 and E-29. As in former years, your Squibb representative invites you to visit the Squibb booth where a comfortable lounge will be provided.

R. J. Strasenburgh Co.
Booth D-8

Mental depression may give rise to influences and have effects which extend far beyond the individual patient. As an accepted tool for further exploration of this difficult problem and as a recognized aid in treatment, Raphetamine Phosphate, brand of racemic amphetamine phosphate monobasic, will be featured at the R. J. Strasenburgh exhibit.

Strong Cobb & Company, Inc.
Booth D-3

Ampins (automatic ampul injectors) consist of *ampul, syringe and needle—all in one pre-sterilized* unit, ready for instant use. Also of interest in booth D-3 will be the new aluminum Emergency Kit, containing many of the commonly used emergency drugs, including morphine and codeine. The administration of parenteral injections automatically is simplified with this new disposable unit.

U. S. Vitamin Corporation
Booth C-8

Here you will see the "oil-in-water" demonstration of natural vitamin A oil in water solution—a vitamin technical achievement pioneered by the U. S. Vitamin Corporation Research Laboratories. While at the exhibit, taste for yourself a new and different sodium-free salt substitute, Co-Salt, which actually tastes like salt, looks like salt and sprinkles like salt—a boon to your patients on restricted sodium intake.

Varick Pharmacal Co., Inc.
Booth E-30

E. Fougera and Company and its division, Varick Pharmacal Company, invite physicians to visit booth E-30 and discuss with professional service representatives new preparations of importance to everyday practice. Descriptive literature and samples of all products *will be available.*

Walgreen Drug Stores
Booth B-11

Prescriptions grow in importance every day as medical science discovers new drugs. Well aware of this growing importance, Walgreen's will feature the Walgreen Pharmacist, who keeps abreast of these new scientific developments as they occur. His training and experience—combined with up-to-the-minute pharmacy knowledge—assures a uniformly dependable prescription service. Professional representatives at the exhibit will be happy to serve in every way possible—to "compound" a happy meeting for you.

Wallace & Tiernan Products, Inc.
Booth B-20

Featured items at the Wallace & Tiernan exhibit will be: Desenex, a well-known undecylenate preparation for superficial fungous infections; Salundek, for tinea capitis; Sotradecol, for effective sclerotherapy in the injection treatment of varicose veins and internal *hemorrhoids;* Azochloramid, a time-tested chlorine antiseptic; and Monomestrol, an orally effective, well-tolerated synthetic estrogen.

Warner-Chilcott Laboratories
Booth E-24

Two cardiovascular agents will be featured at the Warner-Chilcott booth. Medical representatives and research personnel will welcome an opportunity to discuss Methium, to lower blood pressure; and Peritrate, to prevent attacks in angina pectoris.

White Laboratories, Inc.
Booth A-21

Gitaligin, described as a digitalis preparation of choice will be on display at booth A-21. White's representatives will appreciate the opportunity to discuss with you the clinical background and therapeutic merit of this and their other outstanding products.

Wilson Laboratories
Booth B-5

Purified Corticotropin-Gel Wilson—the only Corticotropin-Gel accepted by the Council on *Pharmacy* and Chemistry of the American Medical Association—is the featured product here. Representative at the booth will tell you why Purified Corticotropin-Gel Wilson and Corticotropin Solution Wilson exert the full therapeutic spectrum with recognized notable safety at a *cost of less than 3½* cents per unit of clinical activity.

Winthrop-Stearns, Inc.
Booth A-25

Winthrop-Stearns, Inc., will feature large, three dimensional plastic, transparent models as well as translucent anatomic drawings in full color by Leon Schlossberg of Johns Hopkins University. These include: The Circulatory System (with particular reference to shock); the Biliary Duct System (with reference to oral cholecystography and direct cholangiography); The Path of Pain in the Central Nervous System; *the Fetus at* Term; the Gastro-Intestinal Tract; and the Bronchial Tree (with particular reference to asthma).

Wisconsin Alumni Research Foundation
Booth F-12

Continued research on a new development in the anticoagulant field will be shown at the Wisconsin Alumni Research exhibit. Clinical investigation has shown its value in thrombotic emergency and in surgery. The results of further investigation of the action of aspirin, as well as its possible action in the hypothalamus-pituitary-adrenal chain, are also discussed at the exhibit. Reprints on some of this work are available.

Wyeth Laboratories
Booth B-1

Wyeth will exhibit Plavolex, 6% solution of dextran, a highly efficient Plasma Volume Expander, for use in shock where the circulating blood volume is decreased, as following traumatic injury, burns or during surgery. Plavolex eliminates the danger of viral hepatitis and is ready for immediate use. Also featured will be Bicillin Oral Suspension, palatable, stable, ready-to-use; and Bicillin Injection giving two-week blood levels on a single injection, effective in treatment and prophylaxis.

PHYSICAL MEDICINE AND REHABILITATION

The Burdick Corporation
Booth B-8

Celebrating their 40th anniversary the Burdick Corporation in B-8 will present their line of physical medical equipment. A feature of special interest will be their EK-2 Direct-Recording Electrocardiograph.

The DeVilbiss Company
Booth C-12

The DeVilbiss Company of Somerset, Pennsylvania *welcomes your visit to its exhibit in* booth C-12. Recently developed professional and prescription types of atomizers, nebulizers and vaporizers will merit special attention.

H. G. Fischer & Co.
Booth B-16

Latest models of Modern X-ray, F. C. C.-approved and Council-accepted physical medicine and rehabilitation equipment keynote the H. G. Fischer display. Representatives in attendance will welcome an opportunity to give demonstrations and quote today's low prices. Your visit will be appreciated.

(Continued on advertising page 74)

REPORTS OF OFFICERS

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

The following annual report of the Board of Trustees is respectfully submitted.

Report on Matters Referred by House of Delegates

Resolutions on Portrayal of Physicians in Television and Radio Advertising.—In conformity with the recommendation of the Reference Committee on Miscellaneous Business, adopted by the House of Delegates in June, 1953, the Board of Trustees referred the Resolutions on Portrayal of Physicians in Television and Radio Advertising and the recommendation of the Reference Committee to the Department of Public Relations in order that a meeting might be arranged to which mutually interested parties in the radio and television industries would be invited.

A number of conferences have been held with the National Association of Radio and Television Broadcasters, and the following excerpt from the Television Code was discussed:

> When dramatized advertising material involves statements by doctors, dentists, nurses or other professional people, the material should be presented by members of such profession reciting actual experience, or it should be made apparent from the presentation itself that the portrayal is dramatized.

The NARTB has indicated complete willingness to cooperate with the American Medical Association in every possible way in an effort to eliminate, or, at least, to curtail, the improper portrayal of physicians in television and radio. If in the future an individual physician notes any portion of a television or radio program that seems to be in conflict with the code quoted above, he should communicate with the headquarters office, which will in turn confer with the NARTB.

Attention is called to the editorial published in the June 27, 1953, issue of The Journal mentioning the legitimate complaints of physicians regarding such advertising and the action of the House in this regard.

Resolution on Derogatory Article.—A Resolution on Derogatory Article, introduced by Dr. John P. Culpepper of Mississippi, was adopted by the House in June, 1953, and referred to the Board of Trustees "for implementation." The resolution in question protested the misinformation and "libelous accusations" contained in an article entitled "The Doctor Cartel, an Urgent Problem," which appeared in the May, 1953, issue of "Home Life," a nationally circulated magazine published by the Southern Baptist Convention.

In response to the resolution, the Board of Trustees assisted in the preparation of an article entitled "The Truth About Our Doctor Supply" by Mr. Ira Porter, which was published in the September, 1953, issue of the Southern Baptist Convention periodical. Mr. Porter is the executive vice-president of the Louisville Trust Company, a member of the Deer Park Baptist Church in Louisville, president of the Board of Directors of Blue Cross, a trustee of the Kentucky Baptist Hospital, and a trustee of Georgetown College.

Resolution on Remarks of Commander of American Legion.—A resolution presented by the Reference Committee on Legislation and Public Relations as a substitute for one introduced by Dr. Richard L. Meiling, Ohio, which was withdrawn after introduction, and which had to do with remarks made before the House of Delegates in June, 1953, by Mr. Louis K. Gough, Commander of the American Legion, provided that "the true facts concerning equalization pay for physicians, dentists, and veterinarians serving in the Armed Forces and the U. S. Public Health Service" be made public. The substitute resolution was adopted by the House, and was referred by the Board of Trustees to the Editor of The Journal. An editorial incorporating factual data concerning "equalization pay" was published in The Journal for Oct. 17, 1953.

Resolutions on Compact of Western States for Higher Education (S. 1515).—At the June, 1953, meeting of the House of Delegates resolutions were introduced by Dr. Raymond F. Peterson of Montana urging the House to endorse S. 1515, 83rd Congress, and to encourage its passage. The bill authorized the establishment of a Western Interstate Commission for Higher Education, which would in turn be authorized to stimulate the establishment and maintenance of various courses including medicine, dentistry, etc., by certain western states.

The Reference Committee on Legislation and Public Relations recommended that the resolutions be submitted to the Committee on Legislation for study and necessary action, and they were so referred by the Board of Trustees. The first meeting of the Committee on Legislation following the referral was held on Sept. 26, 1953. Prior to that meeting the bill in question was enacted into law (Public Law 226, 83rd Congress, approved Aug. 8, 1953).

Referral of Resolutions.—The following resolutions, adopted by the House of Delegates in June, were referred by the Board of Trustees for study and report to the councils, committees, and individuals indicated:

Resolutions on Advertising of Medical Products, introduced by Dr. Wendell C. Stover of Indiana, to the Editor of The Journal;

Resolution on Proposed 23rd Amendment to Constitution of United States (H. J. Res. 123), introduced by Dr. Harlan English, of Illinois, to the Committee on Legislation;

Resolution on Clarification of Section 5 of *Principles of Medical Ethics*, introduced by Dr. Millard D. Hill of North Carolina, to the Council on Constitution and Bylaws;

Resolution on "Doctor-Draft" Law, introduced by Dr. A. H. Aaron of New York, to the Council on National Emergency Medical Service;

Resolution on Amendment of Federal Narcotic Act to Provide for Dispensing of Codeine Mixtures and Compounds on Oral Prescription, introduced by Dr. Raymond M. McKeown of Oregon, to the Council on Pharmacy and Chemistry;

Resolution on Regulation of Nursing in Veterans' Hospitals, introduced by Dr. James Stevenson of Oklahoma, to Dr. Thomas P. Murdock, representative of the association on the Joint Commission for Improvement of Care of the Patient;

Resolution on Crippled Children's Programs, introduced by Dr. Cleon A. Nafe of Indiana, to the Washington Office of the Association; and

Resolutions on Annual Medical Progress Day, introduced by Dr. R. J. Azzari of New York, to the Department of Public Relations.

Final reports have not yet been received on the above-mentioned resolutions, but it is hoped they will be available in time to be included in a supplementary report of the Board of Trustees to the House of Delegates.

Privilege Tax by Hospitals

The action of the House of Delegates in December, 1952, in condemning the practice of requiring all physicians using a hospital to pay to it a certain percentage of their fees received from hospitalized patients was transmitted to the American Hospital Association. In a communication from the American Hospital Association it is indicated that its board of trustees concurred in the action of the House of Delegates that the American Hospital Association went on record on June 22, 1947, as being opposed to the practice of assessing members of medical staffs for the day-to-day operation of the hospital; and that its membership has been so advised.

Attendance at Meetings

It is apparent from a review of the agendas of the Board of Trustees that requests for representatives at meetings and on committees of various national organizations are increasing in number. These invitations have in most instances been accepted, and if at all possible members of the Board of Trustees or general officers have been appointed.

Also, due to the increasing number of proposals of importance to the medical profession that have been introduced into the Congress during the past year, as well as studies being conducted by special committees of committees of the Senate or the House of Representatives, the activity of the Association in legislative matters has correspondingly increased. Inasmuch as the Board of Trustees decided a short time ago that either a trustee or general officer must be in attendance at congressional hearings to present the official position of the Association, the demands on the time of the trustees and officers have multiplied. Details concerned with the appearance of witnesses before congressional committees will be found in the report of the Committee on Legislation.

San Francisco Meeting

The San Francisco Medical Society nominated Dr. Edmund J. Morrissey as General Chairman of the Local Committee on Arrangements for the San Francisco Meeting to be held June 21 to 25, 1954, and the Board of Trustees unanimously confirmed the nomination.

Report of Assistant to the General Manager: Department of Public Relations

The public relations program of the American Medical Association in 1953, the first full year following termination of the National Education Campaign, was designed to emphasize the positive, constructive activities of the Association aimed at serving both the profession and the public. With an expanded staff, the Public Relations Department was able to stress the affirmative by continuing and improving its existing services and by initiating several new projects and activities. The general objectives were as follows:

1. To increase public understanding and support of the medical profession by keeping the people well informed on the policies, objectives, and positive programs of the American Medical Association.
2. To increase professional understanding and support of the American Medical Association by making physician members better acquainted with the objectives, activities, and available services of the Association.
3. To improve physician-patient relationships by supplying physicians with practical ideas and suggestions for better public relations on a personal, individual basis in the office, home, hospital, or clinic.
4. To encourage and assist the state and county medical societies in the maximum development of constructive, effective public relations programs at the grass roots level.

To promote the maximum expansion and improvement of all sound programs to solve the economic problems caused by illness and to make medical service more widely distributed and more readily available.

ADVISORY COMMITTEE

During 1953 four meetings were held by the Advisory Committee to the Director of the Department of Public Relations, which is composed of nine executive secretaries and public relations directors of constituent state medical associations. The advice and suggestions given by this committee to the Director have been of great value in formulating programs and projects that will best meet the public relations needs of the state and county medical societies and best serve the national public relations of the American Medical Association.

The present members of this Advisory Committee are as follows:

Mr. John Hunton, Chairman (1952-1953)
Executive Secretary, California Medical Association
Mr. Harvey Sethman
Executive Secretary, Colorado State Medical Society
Mr. Charles Nelson, Chairman (1953-1954)
Executive Secretary, Ohio State Medical Association
Mr. Hugh Brenneman
Public Relations Counsel, Michigan State Medical Society
Mr. Merrill C. Smith
Executive Secretary, Nebraska State Medical Association
Mr. James T. Barnes
Executive Secretary, Medical Society of the State of North Carolina
Dr. John F. Conlin
Director of Medical Information and Education, Massachusetts Medical Society
Mr. Lester Perry
Executive Secretary, Medical Society of the State of Pennsylvania
Mr. Rowland B. Kennedy
Executive Secretary, Mississippi State Medical Association

PRESS RELATIONS

The rapidly growing interest of the American press in medical news continued to mount and reached a new high during 1953. This was clearly demonstrated at the annual meeting in New York in June, where the registration of 185 reporters and writers went far beyond the previous record mark of 110 at the 1952 annual meeting in Chicago. Many newspapers that never before had assigned reporters to an American Medical Association meeting were represented by staff writers.

Following the New York annual meeting an unusual and highly complimentary article was carried by *Editor & Publisher* magazine, the "Bible" of American journalism, on how the American Medical Association handles press relations at a big medical meeting. One science writer was quoted as saying that "the A. M. A. does the best job in the world."

The same kind of press service, just as important but on a smaller scale, was provided at the Denver clinical meeting and again is being rendered at the St. Louis clinical meeting. Major emphasis at both the annual and clinical meetings is placed on the scientific progress of medicine, with special attention going to policy actions of the House of Delegates.

Weekly News Release.—Throughout the year medical news was widely disseminated by means of the weekly news release, which now goes to more than 2,000 newspapers, magazines, wire services, and science writers. In response to a recent survey, almost all of those on the mailing list requested continuation of the service, and many editors volunteered laudatory comments. In addition, the press section during the year put out numerous special releases on organizational developments, and it was called on constantly by the press for information and special materials concerning medicine and public health.

American Medical Association Conferences.—The press section provided extensive advance publicity and press room coverage for such special annual meetings as the Congress on Industrial Health, the Congress on Medical Education and Licensure, the National Conference on Rural Health, and the biennial National Conference on Physicians and Schools. All of these meetings attracted wider press coverage than ever before.

Special Projects.—Press coverage for the special meeting of the House of Delegates in Washington, D. C., March 13, 1953, was handled by key men of the department, with the assistance of the Washington Office staff. The press section of the department also assisted the World Medical Association by preparing news releases on 16 of the papers delivered at the London meeting in August.

MAGAZINE RELATIONS

The American Medical Association in 1953 worked more closely than ever before with magazine editors and free lance writers on articles pertaining to medicine and health. The number of requests for suggestions or help increased to approximately 150. Articles written following such contacts appeared in 35 national magazines of mass circulation, including *Collier's, The Saturday Evening Post, Redbook, Life, Look, Better Homes and Gardens, Reader's Digest, McCall's, Woman's Home Companion, Pageant, Coronet,* and *Farm Journal.* Among the organizational magazines represented were *The Lion, Rotarian, Kiwanian,* and *American Legion Monthly.* Although the majority of the articles were of a health educational nature, many told a positive story about the socioeconomic activities of the medical profession.

Additional Liaison.—Liaison was continued with officers and members of the Society of Magazine Writers. Arrangements also were completed with the Druggist Promotion Service to check all medical copy going into *Beauty and Health,* a new free distribution magazine being issued five times a year through drug stores.

PUBLIC RELATIONS CONFERENCES

Two medical public relations meetings were held in 1953 as a service to state and county medical societies in developing their public relations programs. In September nearly 300 men and women who work with the day-to-day operation of medical public relations programs attended the second Public Relations Institute in Chicago. "New Ways to Better PR" was the theme of the two-day meeting, which provided a practical, short course in public relations technique and methods and also featured a visual display of public relations projects. A digest of the institute proceedings and discussions was distributed to state and county medical society executive secretaries and public relations personnel.

The sixth Public Relations Conference is scheduled for Nov. 30 at the Jefferson Hotel in St. Louis just prior to the Clinical Session. More than 400 physicians and lay executives are expected to attend the conference, designed to outline plans for the 1954 public relations program of the American Medical Association and to provide guidance for the physicians in charge of public relations programs for state and county medical societies.

SERVICES TO COUNCILS, BUREAUS, AND COMMITTEES

During 1953 the Department of Public Relations was able to increase the amount and variety of its public relations services to the Association's councils, bureaus, committees, and departments. These activities, which included special publicity, radio and television arrangements, editorial assistance, and public relations counsel, were aimed at giving both the profession and the public a better knowledge of the year-round, constructive work of the American Medical Association.

Annual Conferences.—In addition to the regular news coverage mentioned under Press Relations, the several American Medical Association conferences were publicized by means of round-up stories in THE JOURNAL, feature stories in *Today's Health,* and other materials supplied to special magazines and house organs. In cooperation with the Bureau of Health Education, the Public Relations Department also arranged 12 radio and television programs at the Industrial Health and Medical Education congresses. As a result of the Department's extensive advance arrangements for the National Rural Health Conference in Roanoke, Va., an estimated 500 network and local radio programs featured or mentioned that meeting.

Veterans Administration Medical Care.—In cooperation with the Committee on Federal Medical Services of the Council on Medical Service, the public relations staff prepared an information kit including a factbook, speeches and other materials on the issue of federal medical care for veterans with non-service-connected disabilities.

Physician Placement.—In cooperation with the Council on Medical Service and the Council on Rural Health, the staff helped in the preparation of a pamphlet entitled "A Doctor for Your Community," now being distributed to aid smaller communities seeking physicians.

Rural Health Digest.—In cooperation with the Council on Rural Health, a staff member prepared a 56-page booklet digest of the Roanoke Conference on Rural Health. The Council distributed it to state and county medical societies and leading farm organizations.

Medical Education.—In cooperation with the Council on Medical Education and Hospitals, a Factbook on Medical Education, based on the 52nd Annual Report on Medical Education in the United States was prepared and distributed to county and state medical societies.

DAILY BULLETIN

The Public Relations Department staff was responsible for the publication of a Daily Bulletin during the New York annual meeting and will do the same at the St. Louis clinical meeting. In New York, 8,000 copies were distributed each day to convention registrants at the Grand Central Palace and various leading hotels. In St. Louis, as at the Denver clinical meeting in 1952, 3,000 copies will be distributed on each day of issue.

"YOUR DOCTOR" FILM

A 16 mm. version of the RKO-Radio film "Your Doctor" was made available in 1953 for showing to schools, churches, and club groups through the booking facilities of Modern Talking Picture Service. Approximately 1,200 individual bookings were made, and the film was shown 2,000 times to a total audience of 130,000 persons. This project was conducted jointly with the Committee on Medical Motion Pictures.

TELEVISION FILMS

The Public Relations Department cooperated with the Bureau of Health Education and the Committee on Medical Motion Pictures in providing a new series of films to be shown on local television stations by state and county medical societies. The Department produced an announcement brochure and kits of promotional material to implement the use of the television films.

"Operation Herbert," a half-hour play starring Jackie Kelk, and a series of six five-minute shorts called "What to Do" were produced under the supervision of the Bureau of Health Education. The American Medical Association obtained television rights to "A Citizen Participates," a new, independently produced 16 mm. film that tells how an individual citizen sparks a community campaign to get a doctor. In September the "Your Doctor" film also was made available for use on television.

The Department and the Bureau of Health Education also worked with Mr. William Hart in coordinating the production of a 26-week series of five-minute spots entitled "M.D." These television films, each of which gives advice on a particular medical problem, were shown on the Dave Garroway program over the NBC television network each Monday morning from June to January.

PROMOTION OF RADIO AND TELEVISION SHOWS

The Public Relations Department represented the American Medical Association in promoting the "March of Medicine" television series sponsored by Smith, Kline and French Laboratories. Four programs are on the 1953 schedule, each telling an accurate and interesting story of medical progress. One was presented in June; others are scheduled for October, November, and December. Special releases and a packet of promotional suggestions for use by state and county medical societies in areas where the shows were telecast were prepared. The Department also worked with the Secretary's Office and the Bureau of Health Education in evaluating story ideas and checking scripts for the series.

The Department also helped to promote "Medicine U.S.A.," a new series of network radio programs presented by the Bureau of Health Education. It informed the state and county medical societies of the new series, issued special stories to the press and to Association publications, and offered suggestions for local publicity in cities where the programs were being carried.

A. M. A. NEWS NOTES

Now in its second year of publication, the monthly clip sheet, "A. M. A. News Notes," is provided as a news service for state and county medical society publications. It contains short, timely news items concerning the activities and services of the Association.

PR DOCTOR

This eight-page public relations news letter with accompanying Exchange packet was issued bimonthly during 1953. In addition, a special Woman's Auxiliary issue was prepared and mailed late in the fall. A number of special enclosures were distributed along with the news letter during the year, including an index of the 1952 PR Doctor, a public relations checklist to help societies evaluate past public relations activities and plan 1953 goals, reprints of several important news stories, and two public relations survey reports.

Public Relations Survey.—A detailed two-page questionnaire requesting information about medical society dues, budgets, personnel, salaries, and activities was mailed in February, 1953, to the entire PR Doctor mailing list. Over 700 responses were received and tabulated. The first survey report distributed in PR Doctor covered dues, budgets, and personnel, and the second gave a résumé of medical society public relations activities.

LITERATURE PREPARATION, PROMOTION, AND DISTRIBUTION

The Public Relations Department distributed more than 2 million pamphlets, booklets and reprints during 1953. These materials were distributed without cost to medical societies, physicians, auxiliary medical personnel, and the general public.

"℞ PR."—A new booklet, "℞ PR," containing two manuals bound into one volume, was completed and mailed to all American Medical Association members in late September. Prepared as a companion piece to "Winning Ways With Patients," it provides physicians with up-to-date information on the human side of medical public relations and on the business aspects of medical practice. Material for the booklet was gathered from a large number of PR-minded physicians, professional management experts, and medical society executives.

"It's Your A. M. A."—"It's Your A. M. A." is a light but thorough inventory of the benefits and services available to physicians through membership in the American Medical Association. It was distributed to all members in mid-October.

"Labor, Politics, and Health."—Based on an article and editorial that appeared in THE JOURNAL late in 1952, the eight-page pamphlet "Labor, Politics, and Health" was produced by the PR Department to refute misinformation presented in a CIO Political Action Committee brochure entitled "'52 Facts on Politics." More than 7,000 copies were distributed to state and county medical societies for local use.

"Guide to Services."—A revision of the American Medical Association "Guide to Services," originally prepared in 1951, was made early in 1953. The new booklet was sent to medical societies, public health officials, and a special public relations list of allied personnel.

"Practice-ly Yours."—A short playlet on public relations in the doctor's office, "Practice-ly Yours," was written for presentation in December, 1952, at the Medical Public Relations Conference in Denver. Since then, the Department has received more than 200 requests, mainly from medical assistants and office nurses, for copies and permission to reproduce the playlet.

Report to the Nation.—The 1953 inaugural address of the President of the Association, "American Medicine's Report to the Nation," was reproduced in attractive pamphlet form, and 10,000 copies were printed for distribution to the state and county medical societies, editors of medical journals, newspaper editorial writers, and others requesting copies.

Continued Distribution.—The Department continued to make extensive distribution of previously published literature such as "Your Money's Worth in Health," "Winning Ways with Patients," "The AMAzing Story," "A Doctor for You," "Which Way America?", and "ILO Spells Danger."

Reprints.—In connection with PR Doctor and other special projects, the Department prepared approximately 75 reprints of newspaper and magazine articles during the year.

Field Service

In 1953 field service emphasis was on county medical societies. Out of a total of 84 visits, 43 were to component societies. The field service visits provided a valuable interchange of ideas and information between the state and county societies and the American Medical Association. Department staff members spoke at society meetings, provided public relations counsel, supplied up-to-date information on Association activities and policies, and filled requests for specific materials, aids, and facts.

Information obtained from the state and county societies was extremely valuable in keeping the American Medical Association abreast of medical progress, attitudes, and policies in the grass roots, and it also provided timely materials for the PR Doctor and Exchange and for loan packets and reference files.

Staff members while in the field contacted numerous lay leaders and organizations in addition to medical groups. Here again, the interchange of ideas and information concerning medicine worked to mutual advantage and helped to build good will for the state and county medical societies as well as for the American Medical Association.

Press Service for President

A new service was initiated by the Public Relations Department in January, 1953, with the addition to the staff of an executive assistant to act as press secretary to the President and President-Elect of the American Medical Association. In addition to the direct handling of press, radio, and television relations for the President and President-Elect while accompanying them on their travels, the press secretary also worked closely with the state societies on advance publicity and arrangements. He aided in coordinating itineraries of the President and President-Elect and in answering the large volume of correspondence from the general public.

PR Series in Today's Health

Another new project started in 1953 was the series of public relations articles prepared by the Department for publication each month in *Today's Health.* The basic purpose of the series, which began with the April issue, is to bring out in readable, feature story style the many American Medical Association activities designed to serve the cause of better health in America.

Presidential Inaugural Ceremony

The Public Relations Department for the first time handled all arrangements, promotion, and publicity connected with the inauguration of the new President of the Association. The inaugural ceremony at the New York annual meeting was broadcast by most stations on the ABC radio network. The Department arranged the entire inaugural program, which included the CBS "Dr. Christian" radio program and presentation of the 1953 American Medical Association Distinguished Service Award. A citation for his portrayal of the typical family doctor was presented to Jean Hersholt, star of the "Dr. Christian" program.

In addition to the regular coverage of the President's inaugural address by the press section, a special news release was distributed in mat form to a selected list of 5,000 weekly newspapers and in mimeographed form to more than 1,200 radio stations. To date, press clippings of the mat have been received from over 500 of the weekly newspapers, and over 100 radio stations have reported using the release in news broadcasts.

Women's Activities

The Department provided public relations counsel and suggested program materials for woman's auxiliaries and other women's groups requesting such services. With the objective of intensifying the Department's liaison with various woman's club groups, a study is being made of the women's activities programs of several industrial concerns. A major and successful project undertaken during the year was participation in the May, 1953, convention of the National Federation of Women's Clubs in Washington, D. C. The Department prepared and distributed nearly 1,000 special kits for program chairmen, containing suggested program materials and booklets as well as a comprehensive listing of American Medical Association literature, exhibits, films, and speakers to aid in building club programs.

Guided Tours

Continuing the program of many years standing, which was placed under the supervision of the Public Relations Department last year, a specially trained staff of 12 young women guided almost 400 physicians, employees, and nonprofessional visitors on tours of the Chicago headquarters building. The visitors represented 37 different states and 36 different foreign countries. The purpose of the tours is to promote good will by interpreting the myriad services and activities of the American Medical Association.

General Services

In addition to the specific projects and activities already mentioned in this report, the Public Relations Department during the year provided a wide variety of editorial, research, and counseling services to the members of the headquarters staff, the officers and trustees of the Association, state and county medical societies, and individual physicians. The Department also devotes a great deal of time to answering requests from the general public for information on medical public relations subjects and on the policies and activities of the Association.

Secretary's Office.—The Department works closely with the Secretary and General Manager's Office on all phases of the Association's public relations program. The Department continued to assist in the preparation of the Secretary's Letter, which goes out each week to more than 3,500 national, state, and county medical leaders. A new service, initiated at the New York annual meeting, was the writing and distribution of a general roundup story on the proceedings of the House of Delegates. This story was sent out on the last day of the meeting to all delegates, officers, trustees, and editors of state journals and county bulletins.

The Staff

The activities described in this report have been handled by a staff of 20 people, including secretarial and clerical help. Three experienced public relations writers were added to the staff late in 1952 and in early 1953 to assist in carrying out the expanded public relations program.

Conclusion

The Public Relations Department believes sincerely that medicine's positive story now is being told more effectively in more ways to more people than ever before. The Department wishes to express its appreciation to the officers and Board of Trustees of the Association for their cooperation and support and to the many departments and staff members at Association headquarters who have assisted in developing a well-rounded public relations program.

Report of Council on Industrial Health

In December, 1952, the Council on Industrial Health appointed a Committee on Scope and Objectives to evaluate progress and reexamine purposes of the Council. Much thought and action have been expended in this direction during the past year. The original charter and present status of the Council as a standing committee of the Board of Trustees have resulted in a satisfactory and effective administrative position. Every reasonable facility has been provided for the Council to carry out its early and later directives. However, the rise of industrial medicine as a specialty, the expanding interest of labor in health and welfare, the basic necessity for teamwork between industrial physicians and private practitioners, the increasing complexity of industrial technology and the continuing demand for competent professional assistance by management have impelled the Council to pause and take stock.

In the opinion of this Committee on Scope and Objectives the functions and services of the Council on Industrial Health have tended to concentrate in four major areas—Public Service, Medical Education and Relations, Scientific Development, and Interprofessional Relations.

Public Service concerns itself with organized labor, organized management, trade associations, governmental agencies, voluntary health and welfare groups, and with other activities not primarily medical or professional in character. Subcommittees dealing with emergency services, workmen's compensation, rehabilitation, and medical care operate within this jurisdiction.

Medical Education and Relations has to do with contacts and joint activities with medical organizations, such as agencies within the American Medical Association and in the states and counties, and with special societies both national and regional. A major responsibility is to encourage all phases of industrial medical education and to maintain lines of communication with the teaching centers.

Scientific Development deals with the preventive, hygienic, and clinical aspects of industrial medicine and industrial health, with emphasis on research and its application, determination of prevailing expert opinion, reviews of current knowledge, nomenclature, new developments, and liaison with allied scientific bodies. Subcommittees include dermatology, ophthalmology, cancer, industrial trauma, and occupational diseases.

Interprofessional Relations provides contact with and leadership to industrial nurses, engineers, safety men, chemists, hygienists, psychologists, personnel directors, and social scientists. Subcommittees are needed to deal with human relations and environmental hygiene and safety.

The Committee on Scope expects to recommend that the present committee structure of the Council be altered to fit this organizational scheme and that staffing be arranged with the requirements of these committees in mind. Specific assignments to these committees would involve such subjects as improved relations with labor, management, and government, evaluation of the part to be played in industrial health by the biological, physical, and social sciences, a better definition of the industrial health team, ultimate relationship between occupational and nonoccupational disability, the dynamics of extending curative medical services into rehabilitation and replacement, and the practical implementation of extending preventive medicine into the health problems of apparently well people. In any case, certain basic objectives of the Council must be preserved. Steady improvement in professional standards and results will always be a primary purpose. The elimination of all roadblocks between the industrial physician and the private practitioner is as important as ever. We want to continue to see to it that industrial health problems receive their proper share of attention and understanding as a major element in the provision of medical services and in community health resources.

Small Plant Health Program

Casualty insurance companies underwriting workmen's compensation risks have wide acquaintance with and entré to small business establishments. Representatives of the major casualty insurance trade associations have met with the Council and have agreed to develop a cooperative program. The intention is to create genuine understanding of industrial health objectives by small plant owners, commercial establishments, and others. It has been considered wise to prepare a short, attractive, readable brochure, which would define the advantages of an industrial health service in simple, credible terms. Such a presentation would stimulate interest, which in turn would be satisfied by more extensive information provided through a variety of sources. It was also decided to set a pilot plan in operation in a receptive area in which good working relations already exist between medicine, insurance, and industry. It is expected that such a trial balloon would point up essential modification in the event of more widespread activity.

The National Safety Council has a closely related objective in its promotion of improved safety standards in small plants. The extensive contacts enjoyed by this national organization should provide many other convenient avenues for the spread of informative material to small plant proprietors. Because of this similarity in purpose it is thought that educational and promotional campaigns might be integrated. The staff of the Council has also been asked to serve as consultants to the National Safety Council in the preparation of "Safetygrams," which are very effective forms of visual education dealing with accident prevention and the management of common emergencies. A proposal has been submitted that material of this kind be issued under the joint sponsorship of the Council on Industrial Health and the National Safety Council. The House of Delegates has urged cooperation with the National Safety Council in all aspects of its accident prevention program. The two projects noted above can be regarded as examples of many other similar types of mutually helpful activity.

The extension of industrial health activity to small plants presupposes the availability of a goodly supply of qualified general practitioners. The Joint Committee previously described in Council reports, made up of representatives of the American Academy of General Practice and the Council, has had an opportunity to participate in a practical demonstration of teaching methods. A symposium designed for general practitioner indoctrination was held at the Harvard School of Public Health. A full transcript of the lectures and demonstration has been secured and distributed to each state medical society, and to each medical school. In addition, sources of practical experience and instruction have been mobilized and will be available in the course of time in many parts of the country.

Industrial Health Councils

The American Medical Association has endorsed the principle of community health councils. Two sizable communities in the South have developed local industrial health councils, which provide a variety of services in the form of health education and certain forms of screening examinations. Direction is supplied by representatives of industry. The purposes and methods have been approved by state and local medical societies. Facilities and personnel to supply these services have in part been made available through public and voluntary health agencies. In this way services have been provided to small plants at a very modest per capita charge. Since this form of community mobilization for industrial health service seems to be a useful modification of the community health council principle, the Council has undertaken to study these programs with great attention with the possibility of implantation elsewhere in mind. A special conference on local industrial health councils was a feature of the 13th Annual Congress on Industrial Health. An abstract of this conference will shortly be available for the information of other communities and local organizations.

Health Home Council

In accordance with instructions received from the Board of Trustees, approved by the House of Delegates, additional attention has been given to the implementation of a Health Home Council. The original report which acquainted the House with this development described meetings with representatives from the Edison Electric Institute, the National Electric Manufacturers Association, and others to set up an agency to promote research and to educate the public, industry, and professional groups about work simplification and energy-saving devices for housewives with disabling disease or handicap. The intent of this development was approved in principle, but was referred back to the Joint Committee on Rehabilitation of the Council on Industrial Health and the Council on Physical Medicine and Rehabilitation for further study. Recently a Statement of Objectives and a Constitution and Bylaws have been prepared, all of which are still under study.

Union Health and Welfare Plans

The Committee on Medical Care for Industrial Workers has extended considerably its knowledge of direct medical service plans. Thirteen union health and welfare programs have been visited and reports prepared, which in turn have been checked for accuracy with the executive directors of the plans themselves. An over-all condensed report is in preparation for publication in The Journal. A separate brochure will describe in detail the individual plans for the benefit of those who are interested in full information. Similar visits are being made to management-sponsored plans, with the same end in view.

In mid-September the second Conference on Medical-Hospital Problems in the Bituminous Coal Mining Areas, sponsored by the Councils on Medical Service and Industrial Health, was held in Charleston, W. Va., and was well attended by representatives of the medical societies of Kentucky, Pennsylvania, Tennessee, Utah, Virginia, and West Virginia, and of the United Mine Workers Welfare and Retirement Fund. A report of this meeting will describe the very gratifying improvement in public and medical relations in the Southeastern bituminous coal fields and the remarkable evidences of improved standards of medical and hospital care.

Sickness Absenteeism

The principle objective of industrial medicine is to reduce sickness absenteeism. It is well known that ordinary illness far exceeds industrial accidents or occupational disease as a causative factor. It is in this general area that the need for team work between the industrial physician and the private practitioner becomes most evident. For nearly thirty years the Division of Occupational Health Care of the Public Health Service has collected, interpreted, and published data on lost-time illness in industry, identified as to major diagnostic classifications, duration, and incidence. These statistics are unique and on them are based most of the calculations which make disability compensation plans and even retirement programs possible. Recent reductions in appropriations have made it necessary to discontinue this service. The Council on Industrial Health has been suggested as a likely agency to assume this responsibility. Current studies are being directed to learn the full usefulness of the data, how they may be improved and more widely circulated, and whether or not the American Medical Association is the agency to serve as the point of collection and dissemination.

The production and monetary loss to industry from lost-time illness is enormous. The private medical profession is directly involved because of the need for certification based on a diagnosis and prognosis in order to establish eligibility for sickness benefits. Many complaints are received about uncritical practices relating to certification, especially the unnecessary prolongation of absence due to sickness or surgical procedure. Teamwork between private and industrial physicians is a first essential to betterment.

The Industrial Medical Association has agreed to assist in the documentation of undesirable practices which tend to prolong illness unnecessarily. A committee is now engaged in clarifying the objectives, listing parties at interest, methods of securing supporting data, and ways and means of arriving at a solution.

Professional Relations

The annual conference between the chairmen of the committees on industrial health in the state medical societies and the Council on Industrial Health have proved to be a most effective stimulus to interchange of information and useful activities. The objectives of these conferences are:

1. To exchange information on as informal a basis as possible;
2. To integrate the work of the Council on Industrial Health and the state committees, and to make this relationship a two-way operation;
3. To stimulate the State Committees to list and undertake specific assignments, and
4. To make certain that Industrial Health is given real consideration in the plans and deliberations of state and county societies.

As a case in point, several state medical societies have recently adopted codes of ethics for the physician in industry. To capitalize on this desirable trend, a committee has been appointed to prepare a code adaptable to all states. The source material will consist mainly of the outline on procedure for physicians in industry originally prepared by the Council in 1942 and now greatly in need of revision.

Workmen's Compensation

The Workmen's Compensation Committee of the Council on Industrial Health is presently engaged in making a survey of medical relations under workmen's compensation. To determine the probable value of a nation-wide survey and to work out the technical aspects of collecting the required information, Illinois was chosen as the location for a pilot study. In June an outline of the material to be contained in the survey and a discussion guide were formulated. A study has been made of the actual practices under the statutory provisions of the Illinois Workmen's Compensation and Occupational Diseases Acts affecting medical relations and services. Among the subjects covered are: Medical care, choice of physician, examinations and reports, hospitals and hospital records, medical fees and costs, medical testimony, accident and occupational disease prevention, and rehabilitation.

Information has been developed through personal interviews with representatives of the medical profession, hospital administration, labor, industry, insurance companies, the Bar, and state agencies. Additional information has been obtained from reports, articles and responses to questionnaires.

Estimation of Visual Loss

Work has been started on a revision of the American Medical Association's method of estimating the percentage loss of visual ability under a distinguished committee of ophthalmologists consisting of Edmund B. Spaeth, F. Bruce Fralick and William P. Hughes Jr. The Section on Ophthalmology has extended its encouragement and endorsement.

Report of Committee on Legislation

During the period covered by this report, Oct. 1, 1952, to Sept. 30, 1953, the Committee on Legislation has had six meetings, has analyzed 259 legislative proposals, and has recommended policy positions on 210 of these measures to the Board of Trustees.

Following is an enumeration of the measures on which either oral or written statements were presented during the 83d Congress, together with the names of the witnesses and a brief resume of each proposal.

S. 106 and S. 1514.—A written statement was submitted by Dr. George F. Lull on April 15, 1953, to the Senate Committee on Government Operations stating the views of the American Medical Association on these measures. S. 106 would authorize the establishment of a commission to study the organization and operations of the Executive Branch of the government. Dr. Lull stated that it was the Association's belief that, if properly conducted, such a survey could result in the elimination of considerable overlapping of activities and waste of funds.

It was pointed out, however, that the primary interest of the Association was with S. 1514, which would authorize a study and report concerning all of the present activities in which federal aid is extended to state and local governments, with particular reference to health, education and welfare. The study would involve matters which have for many years been of vital concern to the medical profession because of repeated attempts at governmental encroachment in the field of health. It was pointed out that the Association felt that such a survey is imperative to determine whether there is justification for federal aid in the various fields in which such assistance has been extended during the past few years, whether such activities should be limited and, if so, to what extent, and finally, to permit an over-all appraisal of the ability of the federal government to finance activities of this nature. These two bills were enacted into law (Public Law No. 108 and Public Law No. 109, respectively) on July 10, 1953.

S. J. Res. 1.—Dr. George F. Lull submitted a written statement on Feb. 18, 1953, to the Senate Committee on the Judiciary, outlining the Association's views on this resolution and similar measures designed to amend the United States Constitution relative to the making of treaties and Executive Agreements. The Association believes that some limitation is necessary to avoid any abridgement of the rights enumerated in the Constitution and to prevent the adjudication of domestic issues by such measures.

This resolution in an amended form was reported favorably by the Senate Judiciary Committee on June 15, 1953 and is now waiting action by the Senate.

H. R. 10 and 11.—Dr. E. J. McCormick and Frank G. Dickinson, Ph.D., testified before the House Committee on Ways and Means on Aug. 12, 1953, supporting this legislation which provides for a deferment of tax payments on premiums paid to promote retirement benefits for self-employed and others not covered by existing pension plans. The bills would amend the Federal Internal Revenue Code to allow physicians and other self-employed individuals to deduct from their taxable income those amounts used each year to finance restricted retirement plans. The purpose of the bills is to eliminate the discrimination and inequities existing under present tax laws, by extending the tax deferment privilege to the country's ten million self-employed, and also to millions of employees who are not covered by pension plans.

H. R. 116.—A written statement containing pertinent statistical information was submitted by Dr. George F. Lull to the House Committee on the Judiciary on April 21, 1953. The bill would prohibit the interstate transportation of fireworks into any state in which the sale of fireworks is a violation of local law, unless they are to be used for public displays or other purposes specifically authorized by the laws of such state.

H. R. 303 and H. R. 1057.—A written statement was submitted by Dr. George F. Lull to a Subcommittee of the House Committee on Interior and Insular Affairs on April 21, 1953, presenting the Association's views concerning these bills and urging that they be reported favorably. These bills, which are designed to provide for the transfer of the functions, responsibilities and duties of the Department of the Interior and the Bureau of Indian Affairs relating to the health and hospitalization of Indians to the United States Public Health Service, have the active approval of the American Medical Association. It is the belief of the Association that the transfer of such facilities to the Public Health Service would result in much needed improvements in the health facilities and hospitals available to the Indian population of the United States. Administration of these installations by the Public Health Service would facilitate the recruitment of necessary physicians and allied health personnel and would insure a higher degree of medical care for the beneficiaries of the program.

H. R. 2769.—On April 21, 1953, a written statement was submitted by Dr. George F. Lull to the House Committee on Interstate and Foreign Commerce, urging that the committee report this legislation favorably. The bill would authorize the Food and Drug Administration to inspect factories without first making a request and obtaining permission. It is the belief of the Association that the principle of this bill is a proper one and that the measure should be adopted, provided proper safeguards are included to protect the physician-pharmacist-patient relationship. It was also pointed out that, although it may not be the intention of the sponsors of the bill that this be applicable to anything other than factory inspections, the Association believes that language should be included which will clearly indicate that the bill has no application to confidential business and professional records which have no specific bearing on the enforcement of the Food, Drug, and Cosmetic Act. This bill was enacted as Public Law 217, 83rd Congress, on Aug. 7, 1953.

H. R. 3204.—Dr. George F. Lull presented a written statement to the House Committee on Interstate and Foreign Commerce on June 24, 1953, requesting favorable consideration of this measure. The bill would authorize the United States Public Health Service to admit to its hospitals persons committed by state courts who are beneficiaries of the service or narcotics addicts. On May 30, 1953, the Committee on Legislation considered this bill and recommended its enactment because of the existing shortage of proper facilities for the persons covered by the bill. This action was approved by the Board of Trustees on June 4, 1953.

H. R. 3375.—On June 17, 1953, Dr. David B. Allman testified before the House Committee on Ways and Means relative to the deduction of medical and dental expenses for income tax purposes.

The Committee on Legislation has considered a number of bills introduced during the 81st, 82nd and 83rd Congresses which are designed, in general, to authorize the deduction of all or a larger percentage of medical expenses from gross income for income tax purposes. The effect of this legislation would be to reduce or remove the limitation on such deductions imposed by existing law. Certain of these bills would also redefine the term "medical expenses" to include amounts paid as premiums for prepayment health insurance. The principle involved in all of these measures has been actively approved by the Committee on Legislation and by the Board of Trustees. Although no attempt has been made to work out the details of the formula to be applied, the Association is of the opinion that a greater measure of relief should be provided in this way for those individuals who have suffered from the financial burden resulting from the expense of a serious, long-term illness.

H. R. 4277.—Dr. George F. Lull submitted a letter to the House Committee on Interstate and Foreign Commerce on July 16, 1953, stating the Association's opposition to this bill. He pointed out that the Association endorses the principle of enacting a Pesticides-Residue Amendment to the Federal Food, Drug, and Cosmetic Act in the interest of public health; however, the Association questions whether H. R. 4277 in its present form would provide adequate safeguards or protection against the marketing of foods containing potentially poisonous or deleterious pesticides.

H. R. 4393.—Dr. Walter B. Martin testified before the House Committee on Ways and Means on June 18, 1953, relative to the deduction of college and educational expenses for income tax purposes. The Association strongly urged that the Committee give favorable consideration to this bill which would amend the Internal Revenue Code to allow persons engaged in teaching school or in any other profession to deduct, as trade or business expenses, and in determining adjusted gross income, ordinary and reasonable educational expenses paid or incurred for the purpose of (1) carrying on his profession, (2) making himself better qualified for his profession, or (3) increasing his remuneration from his profession. The amendments would be applicable with respect to taxable years beginning after Dec. 31, 1952.

H. R. 4495.—Dr. Edwin S. Hamilton testified before the House Committee on Armed Services on April 24, 1953, relative to the procurement of medical officers for the Armed Forces. This bill was designed to extend the "Doctor-Draft" law for two years beyond its expiration date of June 30, 1953. The bill also provided for a variety of technical amendments in the present law (Public Law 779, as amended).

In its testimony the Association endorsed a one year extension of the law, recommended that all priority 4 physicians be excused from further liability for service and suggested a number of less important amendments to the bill. On May 20, 1953, Dr. Hamilton again testified on H. R. 4495 before the Senate Armed Services Committee. This bill was approved, with amendments, on June 29, 1953 and became Public Law 84, 83rd Congress.

Reorganization Plan No. 1, 1953

On March 16, 1953, Dr. Elmer L. Henderson presented the Association's position relative to Reorganization Plan No. 1 to a Joint Committee of the Senate and House Government Operations Committees. This Presidential proposal recommended that the Federal Security Agency be elevated to cabinet rank and redesignated as the Department of Health, Education and Welfare. The plan did not propose any changes in the functions of the agency, but did provide for certain top-level personnel changes.

Despite the fact that the Association has advocated for many years and still advocates a separate Department of Health, this Reorganization Plan was endorsed by the Board of Trustees and the House of Delegates as a step in the right direction. The plan became effective on April 11, 1953, in the form of Public Law 13, 83rd Congress.

Reorganization Plan No. 6, 1953

On June 18, 1953, Dr. David B. Allman testified before the House Committee on Government Operations relative to the reorganization of the Department of Defense (Reorganization Plan No. 6, 1953). The Association's interest in this reorganization plan was confined to Section 3, which would authorize the appointment of six additional Assistant Secretaries of Defense from civilian life by the President by and with the advice and consent of the Senate. Although the specific duties of thsee assistant secretaries were not specified in the Reorganization Plan, it was assumed that the assignments suggested by the report of the Rockefeller Committee on the Department of Defense organization dated April 11, 1953, would be favorably considered. It was the recommendation of that committee that one of the proposed assistant secretaries be placed in charge of health and medical affairs with the responsibility for "maintaining high health standards among the personnel of the Armed Forces and for providing and managing hospitals and other medical installations at the smallest possible cost in dollars and professional personnel."

On Feb. 7, 1953, the Board of Trustees of the American Medical Association approved a recommendation of the Council on National Emergency Medical Service that a position as Assistant Secretary of Defense for Health and Medical Affairs be created by law. It was the belief of the Association that the creation of such a position would insure a proper correlation of military and civilian medicine, especially in the matter of apportionment of essential, highly trained health personnel. This Reorganization Plan was approved by the House of Representatives and since it was not rejected by the Senate within 60 days from the date of referral by the President, it became effective on June 30, 1953. Dr. Melvin A. Casberg has since been appointed as Assistant Secretary of Defense (Health and Medical).

Hospitalization Entitlement of Veterans

Dr. Walter B. Martin testified before a Subcommittee on Hospitals of the Committee on Veterans' Affairs of the House of Representatives on July 13, 1953.

It was the recommendation of the Association that Congress restudy existing legislation providing hospitalization and medical care for veterans with non-service-connected disabilities. The Association questioned whether the federal government should continue to engage in a gigantic medical care program in competition with state, local, and private medical institutions and whether the ever-increasing cost of such a program was a proper burden to impose on the taxpayers of this country. It was recommended that legislation be enacted to limit the medical care and hospitalization benefits for veterans in Veterans Administration and other federal hospitals to: (*a*) veterans with peacetime or wartime service whose disabilities or diseases are service-incurred or aggravated; and (*b*) within the limits of existing facilities, to veterans with wartime service suffering from tuberculosis or psychiatric or neurological disorders of non-service-connected origin, who are unable to defray the expenses of necessary hospitalization.

Regional Legislative Conferences

The Committee cooperated with the Washington Office in conducting a series of regional legislative conferences designed to acquaint key legislative personnel in the states with the most important medical legislation before the Congress.

Liaison and Publication Activities

The Committee has maintained close and constant liaison with the committees on legislation of the state and territorial medical associations and has established similar arrangements with major national health associations in an effort to obtain their support and to furnish them with up-to-date information regarding national medical legislation. In order to facilitate the dissemination of such information the Committee has prepared and distributed a monthly "Legislative Review," which is currently being sent to approximately 300 persons.

In addition, a brief review of the bills considered by the Committee and the policy positions adopted are published in The Journal after each Committee meeting.

Appreciation

The Committee wishes to express its appreciation to the Board of Trustees, the Washington Office, and the officers and staff of the Association, as well as the state medical societies, for their cooperation and assistance during the period covered by this report.

Report of Committee on Medicolegal Problems

This is the fourth annual report of the Committee on Medicolegal Problems. During the year the Committee held one meeting at which reports were presented and considered by the several subcommittees. Another meeting will be held, possibly in connection with the St. Louis Meeting.

Subcommittee on Medical Malpractice.—Continued interest is being expressed in the report of this subcommittee entitled "Malpractice and the Physician," and in the exhibit prepared on the basis of this report entitled "Etiology of Medical Malpractice." During 1953, to date, this exhibit has been presented in connection with the meetings of nine medical societies, including the meeting of the National Medical Association held in Nashville in August. Approximately 3,000 reprints of the report of the Subcommittee were furnished without charge to medical schools for distribution to members of senior classes, and more than 500 copies were otherwise distributed.

Subcommittee on Courses in Medical Jurisprudence.—The report of this Subcommittee outlining a suggested course in legal medicine or medical jurisprudence for medical schools was published in The Journal, Oct. 18, 1952. Reprints of this report were sent to each medical school and the responses received by the chairman of the subcommittee indicated that the schools are definitely interested in the subject of presenting more information to medical students concerning the many problems that they will in later life be confronted with which involve medicolegal situations. This subcommittee is now considering the desirability of preparing additional material that may be utilized by the medical schools in connection with the offering of courses to students in the medicolegal field.

Subcommittee on Medicolegal Aspects of Blood Transfusion.—This subcommittee presented its report at the February, 1953, meeting of the Committee. It was accepted by the Committee and was subsequently published in The Journal for April 18. This report is a comprehensive and informative statement summarizing the present status of knowledge concerning the dangers of blood and plasma transfusion. The various untoward sequelae of such transfusions and the preventive precautions that can be taken are discussed in the report in detail. To date, more than 500 reprints of this report have been furnished to hospitals, blood banks, libraries, and individual physicians. This report, it is hoped, will serve to increase further the safety of this important therapeutic procedure.

As pointed out in the report, two of the most pressing problems related to blood transfusion are homologous serum jaundice and bacterial contamination of bank blood. These problems are worthy of more detailed study in order to determine what steps can be taken to reduce the incidence of these dangerous complications of transfusion.

Subcommittee on Forensic Psychiatry.—The chairman of this subcommittee submitted a progress report which was accepted. In this report the chairman reemphasized the desirability of further studies when necessary to explore the legal actions that are taken against psychiatrists in connection with accidents that follow electric shock treatment. The report also reviewed the facts of a then recent Illinois case involving the right of a court to compel the disclosure of information obtained by a psychiatrist in his examination of a patient. In that case the court held that while in Illinois there was no law declaring as privileged those communications that result from the attendance on a patient by a physician, yet the psychiatrist involved in the case was not required to disclose on the witness stand information he received during the course of his examination of the patient.

Subcommittee on the Medicolegal Status of Blood Tests in Disputed Paternity Cases.—Since the publication of the report of this subcommittee in THE JOURNAL, June 14, 1952, 2,200 reprints have been distributed on request. The chairman of this subcommittee was authorized to revise or to supplement this report whenever in his opinion it is necessary.

Subcommittee on Chemical Tests for Intoxication.—The exhibit prepared by this subcommittee, financed jointly by the National Safety Council, has been used on a number of occasions during the year. It has been shown at least sixteen times to medical and other organizations for a total of 184 days. It was displayed by the Board of Education of Los Angeles for three months in the junior high schools of that area. The exhibit has been so popular that a duplicate copy of it has been necessitated.

This subcommittee has also prepared a leaflet entitled "Test Your A.Q. (Alcohol Quotient)—Twenty Questions on Alcohol," and 30,000 copies of this leaflet have been distributed.

At the last meeting of the Committee, the chairman of this subcommittee reported that there had been some criticism of the laws that have been enacted in a number of states providing for the admissibility of chemical tests for intoxication in evidence. He stated that the objection centered around the fact that none of the laws made it compulsory that a person involved in an automobile accident submit to a chemical test to determine if intoxication was an element of the accident. The National Safety Council, the chairman reported, has developed a model law to correct this shortcoming, providing that since driving a motor vehicle is a privilege, the individual who requests a drivers' license should be required to agree that he would, in case of an accident, furnish evidence regarding his sobriety if called on to do so. A failure to comply with such a request would provide grounds for the revocation of his driver's permit. Copies of this law were not available to the Committee for consideration, and therefore no action was taken.

The chairman of the subcommittee represented the Committee on Medicolegal Problems at the Second International Conference on Alcohol and Road Traffic held in Toronto, Canada, Sept. 9-12, 1953. Representatives from India, Australia, South Africa, Korea, and many European countries attended the conference and took part in the discussions.

Subcommittee on Forensic Pathology.—During the year the chairman of this subcommittee attended many meetings in advocacy of the enactment of appropriate legislation to modernize the functions of the coroner system. At the last meeting of the Committee, the subcommittee chairman made a brief report and suggested that the Committee continue its interests in this particular field.

Consideration was given to the development of an exhibit that might be made available to state medical associations illustrating the benefits to be anticipated if such legislation is enacted to place a coroner system on a more scientific basis. No final action was taken with respect to such an exhibit but it is hoped that one can be evolved for there is a great need for it.

In the report of the Bureau of Legal Medicine and Legislation a detailed reference is made to the formulation by the National Conference of Commissioners on Uniform State Laws of a model medical examiner law. Suffice it to say here that the Committee is heartily in support of this program and has cooperated and will continue to cooperate with the conference. In event that such a model act is evolved by the conference, the Committee has under consideration the establishment of a panel of physicians the members of which will be located geographically to assist state medical associations desirous of promoting the enactment of the model law. This is a continuing project of the Committee and further progress reports will be submitted.

Report of Bureau of Legal Medicine and Legislation

Activities of the Bureau of Legal Medicine and Legislation during the year covered by this report have proceeded in accordance, in the main, with a normal pattern. A considerable number of inquiries dealing with a wide variety of problems in the medicolegal field have been received and answered. Over a period of years a stockpile of information has been accumulated in the Bureau concerning medicolegal situations which can be tapped by members of the Association or by their legal counsel.

A very close relationship has been maintained with the Committee on Medicolegal Problems, of which the Director of the Bureau is a member and functions as its Secretary. Obviously, there are many problems of mutual interest and concern to the Bureau and to the Committee, and collaboration is essential.

During 1953 the Director of the Bureau was assigned the additional responsibility of assuming the functions of an executive secretary to the Judicial Council. This responsibility the Bureau has attempted to assume to the end that the work of the Council can be expedited with the least amount of trouble to the Council as a whole or to the individual members thereof.

The Bureau of Health Education during the past year outlined a series of radio transcriptions explanatory of the activities of the several councils, bureaus, and committees of the Association. The Bureau of Legal Medicine and Legislation collaborated in this project by providing background material for the transcription on the utilization of chemical tests for intoxication and, in addition, recording a brief statement indicative of the interest of the Association, expressed through the Bureau and the Committee on Medicolegal Problems, in other aspects of the broad field of legal medicine.

COUGHLIN CASE

In the report of the Bureau of last year, reference was made to a pending case involving the right of a lawyer, George G. Coughlin, Esq., to deduct for federal income tax purposes expenses incurred by him in attending a postgraduate course on taxation. In the report it was said that since the issues involved in the Coughlin case were so similar to the right of a physician to deduct postgraduate medical expenses, the Association had decided to enter into the case as *amicus curiae*. As previously reported, the office of the Commissioner of Internal Revenue denied the right of deduction claimed by Coughlin and the U. S. Tax Court sustained the action taken by the Commissioner of Internal Revenue. The Association filed a brief as *amicus curiae* before the Tax Court.

Subsequently the case was appealed to the U. S. Court of Appeals, Second Circuit, and again the Association filed a brief. The case before the appellate court was argued orally on March 11, 1953, and on April 14 the court in a unanimous opinion reversed the decision of the U. S. Tax Court and held that the lawyer could deduct, for federal income tax purposes, the expenses incurred by him in attending the postgraduate course on federal taxation.[1]

---

[1] Coughlin v. Commissioner of Internal Revenue, 203 F. (2d) 307

In this decision, the U. S. Court of Appeals recited certain facts involved in the case. It reported that the petitioner lawyer, Coughlin, was a member of a law firm practicing in Binghamton, N. Y. This firm was engaged in general practice but did considerable work which required at least one member to be skilled in matters pertaining to federal taxation, and to maintain such skill by keeping informed as to the changes in tax laws and the significance of current court decisions. The partnership relied on Coughlin to keep advised on this subject and in order to do so he attended, during the year in question, an Institute on Federal Taxation which was conducted in New York City under the sponsorship of the Division of General Education of New York University. In so doing, he incurred expenses for tuition, travel, board, and lodging which he claimed as an allowable deduction under the federal income tax laws as ordinary and necessary expenses incurred in carrying on a trade or business.

The Court of Appeals, in deciding for the petitioner, held that he was morally bound to keep informed on advances that occur in the field of federal tax legislation and that his attendance at the session arranged by the institute was a way well adapted to fulfill his professional duty to keep sharp the tools he actually used in his going trade or business. It may possibly be, the court said, that the knowledge Coughlin thus gained increased his fund of learning in general and in that sense the cost of acquiring it may have been a personal expense. The immediate, over-all professional need to incur the expenses in order to perform his work with due regard to the current status of the law, the court thought, so overshadows the personal aspects that it is the decisive feature.

Following the decision in the Coughlin case, the Bureau requested tax counsel to express an informal opinion as to the effect of the decision on the right of physicians to deduct expenses incurred in the pursuit of postgraduate medical education. Tax counsel indicated that the decision is of special significance for the medical profession and stated, in part:

> "The decision of the Circuit Court is not confined to lawyers. It equally applies to the practicing physician who attends postgraduate courses which are similarly designed to refresh his medical knowledge and to keep him informed of recent medical developments. Therefore, in computing his federal income tax a doctor may deduct the expenses of his attendance, namely, the cost of his tuition, travel, board, and lodging.
>
> "However, it is by no means clear that the court's decision covers attendance at postgraduate courses which are designed to advance the doctor into a new area of his profession. For example, there is a good deal of doubt whether a general practitioner may deduct his expenses in attending a postgraduate course in order to specialize in surgery. But this would be the unusual case. Normally, a doctor attends a postgraduate course relevant to the field in which he is practicing and all the expenses which he so incurs are deductible by him."

The government did not appeal from the decision in the Coughlin case and the time within which such an appeal could have been perfected has expired.

UNIFORM MEDICAL LICENSURE

Early in the year the Federation of State Medical Boards of the United States created a Committee to Study the Essentials of a Modern Medical Practice Act, of which Dr. Bruce Underwood of Kentucky was named as chairman. The idea behind the creation of this committee was to make a determined effort to reach an agreement on certain basic essentials that should be contained in a medical licensure law and which could at least in principle be put into effect in all of the states, thus approaching a uniformity lacking at the present time. Dr. Underwood has asked the Bureau to collaborate with his committee to the extent, initially, of making a detailed study of the present medical licensure laws, and the Bureau has welcomed the opportunity to do so. A detailed study is now under way by the Bureau, and results will be given to Dr. Underwood so that he can present a preliminary or progress report to the federation when it meets the early part of next year.

To the Bureau this seems to be a most worth-while project. It perhaps is not possible to have complete uniformity in every detail in the medical licensure laws of the several states, but it is certainly hoped that out of this effort there can be achieved a uniformity in certain essentials of a licensure law.

THE WOMAN'S AUXILIARY AND INCOME TAXES

Many inquiries have been received during the past few years concerning the right of a member of the Auxiliary to deduct for federal income tax purposes expenses incurred in attending official Auxiliary meetings. This specific question has not been decided by the Office of the Commissioner of Internal Revenue. At the request of the executive secretary of the Woman's Auxiliary to the American Medical Association, an application is now in the process of being filed with the Commissioner's office to obtain a definite ruling on this question. The response to the application will be given due notice in THE JOURNAL.

RADIOLOGY AND HOSPITAL PRACTICE

Since the last report of the Bureau, a significant opinion has been rendered by the Attorney General of Ohio concerning the practice of radiology in and by hospitals. The opinion was requested by the secretary of the state medical board. As a premise for the request, the secretary of the board stated that a radiologist had entered into an agreement with an Ohio corporation not for profit operating a general hospital, under which agreement the physician agreed to supervise the operation of the x-ray equipment owned by the hospital and the technicians employed by it in its x-ray department and as to all x-rays taken at the hospital to give his opinion as to the condition of the patient based on the x-rays taken of the patient. These x-rays were to be taken with hospital equipment either by the technicians or in some cases by the physician himself.

For the services of the physician and the use of its equipment and personnel, the hospital bills and collects a fee from the patient according to a set scale of charges. The hospital would pay the physician for his services a fixed percentage of the net income of the x-ray department. The secretary of the board posed two questions: 1. Was the hospital corporation practicing medicine in violation of the law? 2. Was the radiologist guilty of "grossly unprofessional conduct" within the meaning of the medical practice act which defines that term to include the division by a physician of his fee with any other physician or surgeon or with any other person.

After reviewing previous Ohio court decisions and past opinions of his office, the Attorney General concluded that in Ohio a corporation may not directly or indirectly, whether or not organized and operated for profit, practice a profession by hiring licensed members of such profession to do the actual professional work involved. The Attorney General further expressed the opinion that any corporation which charges and collects a fee from patients for medical treatment performed by licensed physicians as employees of such corporation is unlawfully engaged in the practice of medicine. The Attorney General further states:

> "In any contractual arrangement such as we find here between the hospital and the physician, it can scarcely be contended that the hospital is not entitled to a fair compensation for the use of the facilities owned by it and for the non-professional services performed by it. I should think it would be conceded also that such non-professional services may properly include a reasonable compensation to the hospital (a) for its services in billing and collecting the charges made, (b) for the clerical duties of scheduling the use of the equipment by the physician, (c) for the services of the x-ray technicians, and (d) for any other non-professional services involved in the operation of the x-ray department. Accordingly, I conclude that the contract which you have described in the instant case must be held unlawful if it should be determined that the net income received by the hospital thereunder is manifestly in excess of the reasonable value of such use and of such other non-professional services as are supplied by the hospital."

In answer to the second question submitted by the medical board, the Attorney General said:

> "In the event that your board should determine, in the case of any contract such as that here under examination, that the income received by the hospital is manifestly in excess of a fair compensation for the use of the hospital-owned equipment and of the non-professional services supplied by the hospital, such determination will necessarily amount to a finding that a part of such income is attributable to the professional services of the physician. In such case it clearly follows that the physician has made an arrangement to share his fee with another person, and so is guilty of grossly unprofessional conduct."

MEDICOLEGAL ABSTRACTS

The fourth volume of Abstracts of Medicolegal Cases was made available by the Bureau during the year. A fifth volume is in the course of preparation, to include the abstracts that have previously been published in THE JOURNAL from 1947 to 1952 inclusive. These volumes are published pursuant to a resolution adopted by the House of Delegates in 1932. The four volumes already published make available in an accessible form the abstracts of medicolegal cases that have been published in THE JOURNAL from 1926 to 1946.

During the year covered by this report, too, the Bureau has supplied for publication in THE JOURNAL abstracts of significant decisions by courts in the medicolegal field. The following decisions, which have been abstracted in THE JOURNAL or which will be published during the year, warrant brief comment.

In Nebraska, the Supreme Court held that an unborn child is a part of its mother until birth and since it has no juridical existence prior to that time no cause of action can accrue to it when it is born dead. The unborn child's representative, therefore, has no right to sue for the damages, allegedly sustained by an unborn child, under the wrongful death statute of Nebraska.[1] In New York, however, the Court of Appeals held that an unborn viable child had a right to sue for damages sustained prior to his birth.[2]

A regulation of the Board of Regents of the University of Washington was upheld by the Supreme Court of the State which required all students desiring to register to undergo an x-ray examination of the chest for the purpose of discovering possible tubercular infection.[3]

The Supreme Court of Illinois held that a child is a neglected child under state statutes when its parents refuse on religious grounds to permit a blood transfusion. The court sustained the right of the juvenile court to appoint a guardian for the child who is authorized to consent to the blood transfusion.[4] In another case involving religious faith and belief, the Supreme Court of Florida held that a statute relating to compulsory isolation and hospitalization of tubercular persons was not unconstitutional.[5]

In a decision rendered by the Supreme Court of North Carolina it was held that a charitable hospital is not liable for the negligence of its employees in the care and treatment of patients who have accepted the benefits of the charity if the hospital has used due care in the selection of its employees.[6] But in a case decided by the Supreme Court of Mississippi, it was held that a charitable hospital is liable for the negligent acts of its employees that proximately cause the death of a patient even though the hospital exercises reasonable care in the selection, employment, or retention of such employees. In this case a laboratory technician had reversed the labels on two bottles of blood to be used in a transfusion.[7] A private hospital accepts patients under an implied obligation to exercise such degree of care and attention for their safety as the physical and medical condition of the patient may require. In the case of a deranged or delirious patient, held the Court of Appeals of Kentucky, the care and attention extends to safeguarding the patient from danger due to his inability to care for himself.[8] The Supreme Court of Florida held that one who enters a public hospital and pays for the services he receives is entitled to the same protection and has the same redress for wrongs that he would be entitled to had he had the same experience in a privately owned and operated hospital.[9]

A person charged with murder, held the Supreme Court of California, is entitled to be examined by an alienist of his or her choice, such examination to be private and not in the presence of alienists appointed by the court.[10] In a case involving the admissibility of blood tests in a paternity dispute, the Supreme Court of Ohio emphasized that evidence of this sort is admissible only to prove nonpaternity and not paternity.[11] In the opinion of the criminal court of appeals of Oklahoma, chemical tests for determining whether or not an individual is under the influence of intoxicating liquor have gained such scientific standing for infallibility as to justify the admission of expert testimony concerning them.[12]

The Supreme Court of Nebraska held that an osteopath is entitled to a license to operate a hospital as an incident to his practice of osteopathy.[13] In Louisiana, the Supreme Court held that the practice of chiropractic constitutes the practice of medicine, that the state medical practice act was constitutional and that chiropractors must comply with its provisions.[14]

In a case that came before the Supreme Court of Illinois, it was held that an injury that decreases an employee's corrected vision was compensable even though it did not affect his "naked" vision and that the basis for determining the extent of the disability should be the difference between the corrected vision prior to the accident and the highest correction possible after the accident.[15]

A case came before the U. S. Supreme Court involving the induction of a physician under the so-called Doctor-Draft law in which it was held that the inducted physician need not be used as a physician but that he must be qualified for duty within the category which rendered him liable to induction.[16]

Expenses of tuition, travel, board, and lodging incurred by an attorney in taking postgraduate courses in taxation are deductible as ordinary and necessary expenses, according to a decision of the U. S. Court of Appeals, Second Circuit.[17] According to a decision of the U. S. Court of Appeals, Ninth Circuit, the Federal Security Administrator is authorized to require drugs sold in interstate commerce to bear a label proscribing their sale except on the prescription of a physician if the drugs are not suitable for self-medication and are inherently dangerous, such as male and female sex hormones.[18] Humane societies, in the opinion of the Supreme Court of Wisconsin, must surrender impounded dogs to the University of Wisconsin on proper requisition.[19]

MODEL MEDICAL EXAMINER LAW

The Conference of Commissioners on Uniform State Laws created during the year a special committee to draft a model medical examiner law. The chairman is Robert A. Leflar, Esq., Dean of the School of Law, University of Arkansas. The Bureau and the Committee on Medicolegal Problems of the Association have maintained close contacts with this development by correspondence and conferences. Available material has been furnished.

A first draft of such a law was prepared during the summer and considered by Dean Leflar's committee at a meeting held in Boston on Aug. 17 which was attended by the Director of the Bureau, the chairman of the Committee on Medicolegal Problems, Dr. Alan Moritz, and by the chairman of that committee's Subcommittee on Forensic Pathology, Dr. Richard Ford. A number of changes in the first draft were suggested during the course of this meeting, and a second draft was prepared by Dean Leflar.

Later in the week, the second draft was presented to the conference sitting in Committee of the Whole. Still other changes were suggested, and Dean Leflar will prepare a third draft of the model law which will, after appropriate consideration by his committee, be considered by the conference when it meets in Chicago in August, 1954.

This is an important development in which American medicine is greatly concerned. The Bureau will keep closely in touch with it, collaborating with the Committee on Medicolegal Problems.

STATE MEDICAL LEGISLATION

As has been frequently reported, the Bureau keeps in touch closely with state legislation of interest to medicine. Brief abstracts of bills introduced are weekly prepared for publication in THE JOURNAL, and the Bureau maintains adequate files for the benefit of a constituent or component association or society confronted with particular legislative problems. A summary of the more important laws enacted during 1953 of interest to medicine is in the course of preparation and will be submitted to THE JOURNAL for publication.

MALPRACTICE INSURANCE RATES

There were introduced in the House of Delegates at the Denver, 1952, meeting two resolutions having to do with the rates charged by insurance carriers for malpractice insurance. At the suggestion of its reference committee, the House asked the Board of Trustees to direct the proper Council or Bureau to make a continuing study of the professional liability insurance situation and submit a progress report to the House at its next meeting. In accordance with this request, the Board referred the matter to the Council on Medical Service which did submit a progress report at the New York, 1953, meeting.

Following this report the Board directed that the Council on Medical Service and the Bureau of Legal Medicine and Legislation continue a study of this problem and specifically authorized (1) visits to the home offices of insurance companies for the purpose of getting firsthand knowledge of the medicolegal and related problems incident to underwriting professional liability risks; (2) the undertaking of a thorough study of all activities of constituent associations, and component societies where indicated, to determine to what extent formal claim prevention and legal defense programs are in existence; (3) the continuation and extension of liaison with other medical and related organizations and with insurance carriers in an attempt to create a continuing program of reporting claims or suits involving the medical profession. The Board also suggested that all pertinent data resulting from such studies be made available on a continuing basis to the Committee on Medicolegal Problems so that the work of that Committee may be adjusted from time to time.

The Bureau of Legal Medicine has no detailed report to make at this time. It has been collaborating with the Council in this study and will continue to do so. It is assumed that any detailed report is to be submitted will be made by the Council.

Council on National Emergency Medical Service

This report of the Council on National Emergency Medical Service covers the period from Oct. 1, 1952, to Sept. 30, 1953, during which time the Council has represented the Association in connection with medical military affairs and the medical aspects of Civil Defense.

The Council is grieved to report the death of Dr. Frank H. Lahey, Boston, on June 27, 1953, who was a member of the Council from July, 1950, until November, 1952. On Dec. 16, 1952, the Board of Trustees appointed Dr. William J. Baker of Chicago to replace Dr. Lahey as a member of the Council. The Board also appointed Dr. Edgar M. Dunstan of Atlanta, Ga., and Dr. Carroll P. Hungate of Kansas City, Mo., as consultants to the Council.

MILITARY AND SELECTIVE SERVICE ACTIVITIES

Military developments in Korea and other parts of the world, combined with continuing international unrest, have necessitated increased emphasis on the procurement and allotment of physicians for the armed forces. The role of the Council in this activity was particularly heavy because of the scheduled termination of the original "Doctor-Draft" law on June 30, 1953.

"Doctor-Draft" Law.—Although this act has been one of the primary interests of the Council since its passage in September, 1950, the need for close liaison with persons responsible for its administration and for rapid communication with the profession during this year has been particularly acute. During the past six months the Council has received literally hundreds of letters, phone calls, and personal visits from physicians in service, or from those about to be called. Every effort was made to handle these inquiries as promptly and efficiently as possible and to utilize them in effecting many equitable changes in the new law.

The fall meeting of the Council held on Nov. 8 and 9, 1952, was dedicated entirely to the "Doctor-Draft" law, its administration, and the need and desirability for extending such legislation beyond June 30, 1953. Included in the attendance of some 60 persons were the Surgeons General of the Army, Navy, Air Force, and Public Health Service, the Chairman of the Armed Forces Medical Policy Council, the Chairman of the National Medical Advisory Committee to the Selective Service System, and the medical directors of the Selective Service System and the Veterans Administration, as well as representatives of all major national health associations. These officials supplied the Council with information concerning the requirements of the armed services for medical personnel and with current information concerning the need for extending the then existing law.

On Jan. 31, 1953, the Council conducted a special meeting in order further to discuss and clarify its recommendations relative to the proposed extension of the law. Another meeting was held on Feb. 28, 1953, with approximately 50 representatives of the National Medical Veterans Society in an effort to obtain the recommendations of this group.

As a result of these deliberations, the Council recommended to the Board of Trustees that the Association support a one year extension of the law and at the same time suggested fourteen specific amendments. During the months of February, April, and May the Council participated in a series of meetings with representatives of the Department of Defense and in the presentation of testimony to the Armed Services Committees of the House of Representatives and the Senate.

On June 29, 1953, the President signed Public Law 84, 83rd Congress, which extended a revised version of the law until July 1, 1955. The major changes in the new law involve greater recognition of prior military service with the result that a particular registrant may either (*a*) become exempt from liability from service, (*b*) be placed in a priority less vulnerable to immediate call, (*c*) be subject to a reduced term of service, or (*d*) effect a severance of military status within 90 days upon application or after the completion of his period of service by either being discharged or permitted to resign.

On the same day the law was signed, the Council distributed a complete résumé of its provisions to all state medical societies, to the members of the Board of Trustees and the House of Delegates, to State Medical Advisory Committees to the Selective Service System, and to all individual physicians who had previously inquired with respect to the draft law.

Civilian Participation in Military Medical Affairs.—The existence of legislation designed to obtain physicians for military service on an involuntary basis requires close civilian participation in military medical affairs and the greatest efficiency in the utilization of physicians by the Armed Forces. The Council on National Emergency Medical Service, working with medical advisory committees such as the Health Resources Advisory Committee, has been successful in effecting a reduction in the ratio of physicians in military service to troop strength from over 6.0 per 1,000 to 3.7 per 1,000. There is every indication that this ratio will be reduced to 3.0 in the near future. This means that fewer physicians will be disrupted in their civilian practice and, as a result, the continuation of present high standards of civilian medicine will be assured. Inasmuch as the medical accomplishments of the military service since the beginning of the Korean war are the best in the history of the United States, it is apparent that the reduction in the number of physicians in service has in no way impaired the quality of military medical care.

Assistant Secretary of Defense for Health Affairs.—In the interest of even greater civilian participation in medical military planning the Council recommended to the Board of Trustees that a position of Assistant Secretary of Defense for Health and Medical Affairs be created by law. It was the belief of the Council that the creation of such a position would insure a proper correlation of military and civilian medicine, especially in the apportionment of essential, highly trained health personnel. This recommendation was accepted by the Board and forwarded to the Rockefeller Committee then studying the possible reorganization of the Department of Defense. The recommendation was included in Reorganization Plan No.

6, which became effective on June 30, 1953. Since that time, Dr. Melvin A. Casberg has been appointed as the first incumbent to this position.

Survey of Physicians Leaving Active Military Service.—Just over a year ago the Council initiated a continuing survey of physicians being released from active military service. To date a total of 5,635 questionnaires have been sent to such physicians and 3,766, or 67%, have been filled out and returned. It is planned to use the results of this survey as the basis for a series of conferences with representatives of the Department of Defense and the Armed Forces in an effort to improve further the utilization of medical personnel and in the formulation of a more effective voluntary officer procurement. The first of these meetings was held at the Department of Defense on July 31 to discuss the results of the first six months of the survey.

Placement Assistance for Physicians Released from Military Service.—Another project of the Council is designed to acquaint physicians, being released from service, with existing civilian medical opportunities. This placement program has been carried on with the active cooperation of the Department of Defense and the Selective Service System and has proven to be of real service to physicians and state medical societies. As of Sept. 1, 1953, letters have been sent to 4,980 individual physicians. Of this number, 957 have requested further information.

Medical Care for Dependents of Service Personnel.—As one of its continuing projects, the Council has analyzed existing provisions of law granting medical benefits to dependents of service personnel and of proposals to extend such benefits. During the past year, a special advisory committee, under the chairmanship of Dr. Harold G. Moulton, was appointed by the Secretary of Defense to study the question of dependent medical care. The Council is reviewing the report of this Committee and will submit its recommendations to the Board of Trustees concerning implementing legislation which will be introduced early in the next session of Congress.

"Special Pay" for Physicians in Military Service.—During the past year another commission, under the chairmanship of Mr. Louis L. Strauss, conducted a study for the Secretary of Defense to determine the advisability of continuing all types of incentive, hazardous duty and special pays now provided by the armed forces. Included in this study was the special pay of $100 per month payable to physicians in uniform.

In participating in an appearance before this Commission on Nov. 30, 1952, and in appearances before the Armed Services Committee of the House of Representatives and the Senate on April 22, 1953, and May 20, 1953, respectively, the Council strongly advocated the continuance of this pay. Although the "Strauss Commission" filed an unfavorable report, proponents of the special pay, including the American Medical Association were successful in having the authority to make such payments continued until July 1, 1955, through the passage of Public Law 84, 83rd Congress on June 29, 1953.

Universal Military Training.—On July 23, 1953, the President nominated three new members to the National Security Training Commission and named Mr. Julius Ochs Adler as the chairman. The Commission has been directed to restudy and report to the President and the Congress concerning the details of a Universal Military Training Program.

On Aug. 28, 1953, the Council submitted a statement to the Commission and made extensive recommendations with respect to the following health and medical aspects of universal military training:

1. The Continuation of Pre-Professional and Professional Education for Qualified Students;
2. The Performance of Pre-Induction, Induction and Periodic Reserve Physical Examinations by Civilian Physicians or Medical Reserve Officers;
3. Extent of Medical Services to be Provided for Members of the National Security Training Corps: (*a*) Corrective Treatment and Rehabilitation, and (*b*) Medical Care During Period of Basic Training;
4. Status of Members of National Security Training Corps and Reserve Components for Veterans Medical Benefits; and
5. Source and Selection of Medical and Allied Professional Personnel.

CIVIL DEFENSE ACTIVITIES

With President Eisenhower leading the way, there has been a gradual awakening during the past year to the need for an accelerated civil defense program. In his State of the Union Message on Feb. 2, 1953, the President strongly emphasized that in the light of world conditions, civil defense preparedness had become a "sheer necessity." This acceptance of the concept that national defense must include civil defense, coupled with the occurrence of a series of natural disasters and the explosion of a hydrogen bomb by Soviet Russia, has tended to arouse public interest in the problem of medical service in the event of an emergency.

Although the medical profession as a group has completed the preparation of state and local medical disaster plans, there has not been an acceptance of individual responsibility by the average physician. It is, therefore, the intention of the Council to concentrate on this phase of the civil defense program during the coming year.

National Medical Civil Defense Conference.—On Sunday, May 31, 1953, the Council sponsored a medical civil defense conference in New York City, which was attended by approximately 80 persons, including chairmen of State Emergency Medical Service Committees and representatives of county medical societies interested in civil defense affairs. Mr. Val Peterson, Federal Civil Defense Administrator, appeared on the program and outlined his views concerning the future role of civil defense in the United States and the part which the medical profession will be required and expected to play. He praised the profession for its active interest to date and requested that the individual physician be encouraged to participate more actively.

The proceedings of the Conference have been prepared, and to date approximately 500 copies have been distributed.

Medical Advisory Committee to Federal Civil Defense Administration.—In response to an invitation from Mr. Val Peterson, the Federal Civil Defense Administrator, the Council suggested the names of physicians to serve as members of a special committee to advise the Administrator regarding the medical aspects of civil defense. On May 18, 1953, Mr. Peterson advised the Council that invitations had been issued to six of the physicians recommended. For the present, Mr. Peterson will act as chairman of the group.

Survey of State Medical Civil Defense Preparedness.—In December, 1952, correspondence was addressed to the executive secretaries of state medical associations, the chairman of state emergency medical service committees and state and local civil defense officials in an effort to bring up-to-date available information relative to the status of medical civil defense preparedness throughout the country. A compilation was prepared as of June 1, 1953, which has been published in THE JOURNAL and distributed to over 300 interested persons and organizations. The information contained in the compilation reflects the existence of state civil defense legislation; the amount of state civil defense funds and size of staff; the identity of state civil defense officials and medical civil defense leaders; the existence of a written, medical civil defense statewide plan, training manuals, training courses, etc.; the actual assignment of physicians to civil defense positions and the extent to which state plans have been tested by practice drills.

Bibliography of Articles on Medical Aspects of Civil Defense.—In the past several years an increasing number of pamphlets and articles have been published dealing with the medical aspects of civil defense. In response to a number of requests the Council has endeavored during the past several months to prepare as complete a listing as possible of this material. This bibliography, which is now being printed, has been separated into two parts. The first is a listing of the titles of articles on this subject and the second is an alphabetical listing of authors. It is intended that supplements to this bibliography will be prepared on an annual basis.

Participation in Medical Civil Defense Conferences.—The Council has actively participated in a number of civil defense meetings designed to facilitate and expedite local planning. Included are:

(*a*) Meeting of chairmen of State Emergency Medical Service Committees, Denver, Dec. 3, 1952.

(*b*) Civil Defense Conference of Association of State and Territorial Health Officers, Washington, D. C., Dec. 7, 1952.

(*c*) County Medical Societies Civil Defense Conference, Kansas City, Mo., Dec. 13-14, 1952.

(*d*) Refresher Conference, Federal Civil Defense Administration, Washington, D. C., May 6-7, 1953.

Compilation of State Civil Defense Laws.—The Council also conducted a survey of all states to determine the existence of local civil defense acts. Following the survey, which revealed that 47 states had enacted such legislation, résumés of all state laws were prepared and distributed.

MISCELLANEOUS ACTIVITIES

During the past year the Council has continued to maintain close and constant liaison with federal and state governmental agencies and with allied health organizations. All have been extremely cooperative and helpful to the Council in carrying out its responsibilities.

In addition to the preparation of the bibliography referred to above, an effort has been made to obtain, review, and distribute all pertinent medical civil defense literature.

A periodic Information Memorandum has been distributed to the members and consultants of the Council, advising them of the latest civil defense developments and furnishing them with copies of the most recent civil defense publications. A similar Civil Defense Review is dispatched on a monthly basis to a mailing list of over 800 persons, consisting primarily of the chairmen and members of state emergency medical service committees. As a further means of communication, a special section of THE JOURNAL has been dedicated to medical Civil Defense news.

In addition, the members of the Council have authored numerous articles, reports and editorials for THE JOURNAL and other health publications.

COUNCIL MEETINGS

Three full meetings of the Council were held in Chicago on Nov. 8 and 9, 1952, Jan. 31, 1953, and April 18 and 19, 1953. In addition to the Council membership and certain officers and staff members of the American Medical Association, representatives of the major national health associations, and interested government agencies were in attendance.

The executive committee of the Council met on two additional occasions, Dec. 3, 1952, and May 31, 1953, in order to consider urgent matters within the jurisdiction of the Council.

APPRECIATION

The Council wishes to express its appreciation for the cooperation and assistance it has received from the Board of Trustees and the officers of the Association and from the allied professional organizations and agencies of the federal government with which it has worked during the period covered by this report.

Report of Washington Office

The Washington Office reports to Association officials and to the profession as a whole on developments in the Capital. On request, it also advises Association councils and committees on Washington problems. At the same time the Office keeps official Washington informed of Association views and, as an agent of the Board of Trustees, it assists in efforts to get Association policy translated into action by Congress and the federal agencies.

The past 12 months represent the first full year the Washington Office has functioned under its present Director, Dr. Frank E. Wilson. Although there have been changes in the stenographic and clerical employees, the only addition to the staff was Dr. Thomas H. Alphin, as an Assistant Director. Formerly he had been with the Federal Civil Defense Administration. The other assistant director is Dr. C. H. Maxwell. Other staff members include James W. Foristel, legal advisor, George E. Connery, editor, and Malcolm D. Lamborne Jr., assistant editor. A business manager, his assistant, secretaries, and clerks bring the total staff to 17.

To help in establishing and maintaining effective relationships with leaders in Congress and the executive branch, the Board of Trustees appointed a special Federal Liaison Committee. The committee and the Washington staff worked jointly to make and keep contact with government leaders during such transitions as the organization of the Republican Congress, the creation of the Department of Health, Education, and Welfare, the reorganization of the Defense Department and Veterans Administration, the various congressional investigations, and the formation of the Commission on Intergovernmental Relations and the Commission on Organization of the Executive Branch of the Government. During the 12 months the Washington staff has done an increasing amount of work for and with the various Association committees and councils and with the Chicago headquarters staff.

The Office continued to work closely with the Committee on Legislation, supplying it with copies of new bills of medical interest and with background information on the sponsors and the special interests promoting the legislation. This committee found it convenient to meet in the Washington Office several times, as did the Council on Medical Service. The Committee on Blood, of which the Director was for a time secretary, also met in the Washington Office until the committee secretariat was transferred to Chicago. Other official American Medical Association groups with which the Office operates closely include the Bureau of Medical Economic Research, Committee on Medical Motion Pictures, Council on Industrial Health, Council on National Emergency Medical Service, and Public Relations Department. In a number of instances Washington staff members were assigned to develop reports and information on government medical programs for use by councils, bureaus, and committees.

One of the special responsibilities of the Office was to assist in arranging the special session of the House of Delegates, held March 14, 1953, to pass on President Eisenhower's plan for creating the Department of Health, Education, and Welfare.

The successful fight in the House of Representatives to defeat a "rider" to the Veterans Administration appropriations bill is an example of how the Association's views can be brought to the attention of Congress through joint action. Cooperating in the brief but important campaign were the Washington and Chicago staffs, the Committee on Legislation, the state secretaries, and a number of individual physicians. The "rider" would have established a partial pay schedule for veterans hospitalized for non-service-connected cases and would have encouraged a vast expansion of the Veterans Administration hospital system. During this critical period the Washington Office Director, under instructions from the Board of Trustees, sent a series of telegrams and letters first to all members of the House Appropriations Committee, then separate messages to all members of the House, and additional messages to leaders of the House. The A. M. A. Washington Letter was used to alert the profession, and a press release was issued outlining the Association's reasons for objecting to the "rider." The director also called on state secretaries and the Committee on Legislation, urging that all U. S. Representatives be contacted by physicians from their districts. The Chicago staff exerted its efforts in the same direction. After the House vote defeating the "rider," the Director sent a detailed, chronological summary of events to members of the House of Delegates, state secretaries, the Board of Trustees, the Committee on Legislation, and officials at Chicago headquarters.

During the year the staff continued to scan state and local society publications to learn reaction to Washington activities. Also, on request, a number of studies and investigations were made for state society secretaries. A growing tendency was noted on the part of physicians visiting Washington to stop in at the Office, either to obtain information or guidance in a particular field or to learn more about how the Association's affairs were handled in the Capital. The "doctor draft" particularly stirred wide interest, hundreds of inquiries on the subject coming by letter, telegram, telephone, and in person.

When Congress was not in session, members of the Washington staff attended and spoke at meetings of medical and lay groups in various parts of the country. Most important was a two-month tour by the Director, in which he met with medical association leaders at a series of regional meetings arranged in cooperation with the Committee on Legislation. During his travels he conferred with representatives of medical societies from 47 states.

As in the past, a share of the Washington staff's time was devoted to liaison work with other organizations in the health and social fields, such as the American Dental Association, American Red Cross, American Legion, American Hospital Association, and Chamber of Commerce of the United States. The Director is chairman of the American Medical Association's delegates to the chamber.

To improve its reporting service, the Washington Office merged and realigned its publications and purchased better equipment to speed up processing. The merger of the weekly Capitol Clinic and Legislative Bulletin into the present A. M. A. Washington Letter was decided upon only after a study lasting several months. An effort has been made, through judicious selection of material and condensation, to give the readers the same coverage they formerly received in the two publications. Although economy was not the principal motive, the elimination of one weekly publication resulted in a significant financial saving, much of it in postage. A new format also was adopted, providing larger type, a better spacing arrangement, and a new system of headlines. At the same time, provision was made for the Director each week to talk directly to readers through the medium of a brief message titled "The Week in Washington" and carrying his signature. The rest of the publication was continued as an objective report without editorial coloration. All legislation of medical interest is reported in the Letter and followed through Congress as before, with a blue streak along the right edge continuing to identify these legislative pages. In the last session, 274 bills of direct or related medical interest were reported step-by-step in Congress. The first step was to describe the bill's contents, give the date of introduction, and identify the author and name the committee to which the bill was referred. Subsequently the Letter described how the particular legislation fared in committees and in Senate and House. The final step, in the case of bills passed by Congress, was to report date of their signature by the President and the Public Law number assigned to them.

In addition to reporting in the Washington Letter on bills introduced, the Office also sends a more detailed analysis of new bills to members of the Committee on Legislation, the Board of Trustees, and a list of Association officials. Following each meeting of the Board of Trustees at which federal legislation is considered, the Washington Office sends to its complete mailing list a report on the Board's actions on various bills.

A new system was adopted for reporting on special subjects that do not readily fit into the format of the Letter. Whereas formerly such information went out as "Comments" or "Special Bulletins," all of it now appears in the form of Special Reports, where the same policy of factual writing and brevity is observed. Twelve special reports were issued.

As in past years, a number of state and local medical journals reprinted news items and special reports published by the Washington Office. For example, a large number reprinted the special report on the "doctor draft," issued as soon as the new law had been signed by the President. Most journals give the Washington Office credit as the source in reprinting material.

The Washington Office supplies The Journal with a weekly report on Washington news. Although material covered in general is the same as that presented in the Office's news letter, the manner of presentation is considerably different. More background material is included in The Journal news, and there is less emphasis on the often complicated legislative issues. New bills are described for the medical profession in a special column, "Federal Medical Legislation, written by the Washington staff and appearing regularly in The Journal when Congress is in session.

Constant efforts are made to restrict news letter circulation to those who are particularly concerned with or interested in Washington developments. Early this fall, for the second time in two years, the mailing list was screened to eliminate readers who were making the least use of the material. It was anticipated that in this way the publications would be made more effective.

Until June the Washington Office had not engaged in press relation activities, except for answering inquiries from writers. In June, after a conference with officials from Chicago headquarters, it was decided to start news releases on a limited scale in the Washington Office. Since then several press releases have been issued by the Office based on testimony of Association spokesmen before congressional committees or explaining the Association's position on legislative questions.

FEDERAL LEGISLATION

The following important medical legislation was before Congress this year:

A Department of Health, Education, and Welfare was created under the reorganization act and became effective April 11, 1953. This full-fledged department, which replaced the Federal Security Agency, gives the new Secretary cabinet status. The House of Delegates, at a special meeting, decided not to oppose the plan, but to maintain the Association's long-standing objective of a Department of Health. Meanwhile, the Association is closely observing how the new department operates. Important in the reorganization was the appointment of an assistant to the Secretary who advises the Secretary on all programs of the department regarding medical matters. Dr. Chester S. Keefer, Brookline, Mass., was sworn in on Aug. 12 to fill this position.

The "Doctor-Draft" act, due to expire last June, was extended for two additional years and amended to remove certain injustices. Shorter periods of obligated military service were effected and previous service not heretofore recognized will in the future be credited. The American Medical Association kept close touch with this situation, and many of our recommendations were accepted.

The Social Security Act became the target of a study which promises broad revisions. A special subcommittee of the House Committee on Ways and Means, under the chairmanship of Rep. Carl T. Curtis of Nebraska, will be studying revisions of the act throughout the balance of this year. The subcommittee expects to make recommendations during the next session of Congress. The Administration is sponsoring a bill to provide for coverage of certain self-employed persons, including physicians, but this was introduced too late for any action. The Association's official position is in opposition to such extension.

Bills of a medical nature in the field of veterans legislation were numerous. Most important were several dealing with Veterans Administration policy regarding hospitalization of non-service-connected disabled veterans. A subcommittee of the House Veterans' Affairs Committee held lengthy public hearings on this subject, the result of which will be felt next year either in the form of some affirmative action by Congress or a tightening up of the loose policy in admitting for hospitalization veterans with non-service-connected disabilities without looking into ability to pay. The attempt to set up a partial payment plan for non-service-connected cases by means of a rider to the Veterans Administration appropriations bill was made late in the session. The issue came up unexpectedly, and opposition had to be organized rapidly. As noted above, the House voted to drop the rider.

Much interest has been generated in a proposed constitutional amendment respecting treaties and agreements with foreign countries. The constitutional amendment resolution proposed by Senator Bricker and joined in by 63 other Senators has much popular support, including that of the American Medical Association. Lengthy public and closed hearings were held last session, but up to adjournment Senator Bricker and administration representatives could not agree on compromise language. Just before the session closed Senator Knowland, the majority leader, advanced a new suggestion. However, this was not acceptable to Senator Bricker, who said the safeguards are not adequate. Presumably efforts to reach an agreement will be resumed next session.

Pension plans of the Jenkins-Keogh type were discussed during general tax hearings held by the House Ways and Means Committee after adjournment of Congress. The Association was joined with virtually every other national association representing self-employed persons in urging some tax consideration for the self-employed on a parity with existing employee pension plans.

During the tax revision hearings it was urged that changes be made with respect to health expense deductions from income so that individuals might be encouraged to provide against the cost of medical and hospital care in a voluntary manner. Another facet of the same hearings was the subject of tax exemption for postgraduate courses in education. The Association has been urging Congress to permit deductions for physicians who further their medical knowledge with additional schooling.

One of the few "must" bills of the President, restoring to the Food and Drug Administration the right to inspect factories, passed in the closing days of the session. An attempt to authorize Food and Drug agents to inspect prescription files in drug stores was defeated. Several of the drug associations and the American Medical Association had opposed this unnecessary grant of power.

Subjects of former major concern to the Association, given little or no consideration this session, included national compulsory health insurance, federal aid to medical education, free school health services, subsidization of local public health units, and emergency maternity and infant care (EMIC) for families of military personnel.

Two important study commissions authorized by Congress are: (*a*) Commission on Intergovernmental Relations, which will restudy proper functions of federal and state governments in fields of public welfare, health, roads, school lunches, and a host of other federally subsidized (in part) state programs; and (*b*) Commission on Organization of the Executive Branch of the Government, which will look into efficiency in government programs and possibly suggest elimination of certain unnecessary functions. Clarence E. Manion, former Dean, Notre Dame Law School, is chairman of the first group, and Hon. Herbert Hoover of the second.

The next session of Congress certainly will not be devoid of medical legislation. Commitments already made by the administration mean that amendments to the social security law extending coverage to the self-employed, including physicians, will come up for decision. In the same connection, there may be action on the bills to permit the self-employed to defer income tax payments on money paid into retirement funds, as well as action on the proposals to allow deductions for postgraduate education costs. The House Veterans' Affairs Committee may have some legislation to propose on care of non-service-connected cases by the Veterans Administration. The two newly formed commissions may offer bills with medical implications before the next session closes, and it will be surprising if Congress does not take some definite action on the long-delayed Bricker resolution.

Report of Bureau of Medical Economic Research

During the past year the Bureau has published Bulletins 92 to 96 and miscellaneous publications M-70 to M-77. Approximately 120,000 copies of these and earlier bulletins and 120,000 copies of these and earlier miscellaneous items were distributed during the year. The number distributed is again smaller than in the previous year, which probably reflects a continuation of the decline in public interest in controversial questions in the field of medical economics.

Approximately one year ago Everett L. Welker, Ph.D., Associate in Mathematics for five and one-half years, resigned to accept a position in mathematical research in the Department of Defense. On July 15, 1953, he was replaced by Mr. John J. Raymond, Associate in Sociology. A considerable turnover in other personnel, due almost entirely to family and personal reasons, has occurred during a period when the demand for I. B. M. services by committees, councils, other bureaus within the American Medical Association, and outside agencies is increasing.

Since a considerable portion of the Bureau's work is represented by publications, a short summary of each of these publications constitutes the bulk of the annual report. Bulletin 92, "Mortality Trends in the United States, 1900-1949," is an analysis of mortality changes in the general population in the 20th century, of changes in life expectancy and in the age-specific mortality rates by cause of death, and of the decline from national to local status of the problems of maternal and infant mortality. This bulletin involved a considerable amount and variety of computations and has already become a basic reference in the field of vital statistics.

President Truman's Commission on the Health Needs of the Nation completed its study during 1952, but its five volumes were published over a period of several months. The Director of the Bureau was requested to prepare a detailed analysis of each of the five volumes, as he had been three years ago to prepare an analysis of the Ewing report—Bulletin 69, to supplement the statement of the Board of Trustees on volume 1, "Findings and Recommendations" (*J. A. M. A.*, Jan. 24, 1953, page 302-303). This analysis was published in two parts, because all five volumes were not published simultaneously; the analysis of volumes 1, 4, and 5 is Bulletin 93 and of volumes 2 and 3, Bulletin 93A. The general conclusions were that the Truman Commission did not recommend a middle-of-the-road program and did not accept the voluntary health insurance way to the solution of the health problems of our nation. The Director defended his conclusions during the two-day discussion of the report sponsored by the National Health Council in March, 1953. In this task he was assisted by Charles E. Bradley, Ph.D., Associate in Economics.

Bulletin 94, "Distribution of Physicians by Medical Service Areas," is now in the process of being published. The 64-page map supplement, Bulletin 94A, was published during May, and an exhibit based thereon was shown at the New York meeting. This study was initiated during the Director's first year of service, 1946-1947, for the specific purpose of providing a substitute for the traditional and misleading population-physician ratio by county. For the sake of brevity, only three major conclusions will be mentioned: (*a*) Outside a radius of 25 miles from the closest physician in active private practice is ⅙ of the land area of the United States but only ⅙ of 1% of its population; (*b*) the population-physician ratios of the 75 medical service areas (total, 757) which had more than 2,000 persons per physician in active private practice in April, 1950, could have been reduced to a maximum of 2,000 if only 400 large-city physicians had been relocated in these 75 areas; (*c*) in general, the distribution of physicians in relation to the persons they actually serve is far better than is indicated in previous studies of physician distribution. The Director regards this study of medical service areas as a benchmark in the field of medical economic research.

Bulletin 95, "Old and New Base Periods for Medical Care Price Indexes," presents a detailed explanation of the changeover from the so-called "old" Consumer's Price Index to the new version. The adoption of a new base period, 1947-1949, to replace the old base period, 1935-1939, has and will produce some rather ridiculous results; the current prices of women's cotton housedresses, men's street shoes, and haircuts are made to appear cheap and rents and medical care high in price. The Bureau has suggested, therefore, that at least once each year the U. S. Bureau of Labor Statistics be required to publish and to publicize the indexes on both the old and the new base period in order to destroy the illusion of medical care prices being higher than the general level of consumer prices, an illusion created by the shift to a new base period. Several weeks before publication of Bulletin 95, preliminary estimates of several indexes were furnished to the Marshall-Hester studio for use in the new American Medical Association film, "Operation Herbert." This motion picture is built around Bulletin 87, a copy of which actually appears in the picture. The Director and members of the staff assisted in the preparation of the film at many stages, from checking the script to advising on the actual filming. The Director believes that this and other methods of popularizing the research findings of the Bureau should be encouraged.

Bulletin 96, "Pensions for the Self-Employed and the Pensionless Employed," presents the testimony of the representatives of the American Bar Association and the American Medical Association on H. R. 10 and 11 before the House Committee on Ways and Means, Aug. 12, 1953. These four statements, which are generally supplementary, provide a comprehensive and detailed explanation of the Jenkins-(Reed)-Keogh bills to establish a voluntary pension system for the self-employed and the pensionless employed. These hearings culminate many months of activity by the Director and the representatives of other national professional organizations in a loosely knit group called the Coordinating Committee on Pensions for the Professions and the Self-Employed. The enactment of this measure would establish individual retirement plans toward which the government would make no contribution; only the individual himself would make payments. This is its great merit. Five to 10 years after passage of H. R. 10 the contrast between these individual pension plans and the Old Age and Survivors' Insurance pensions would have a sobering effect on the headlong rush toward security. Under the former, every self-employed and pensionless employed person who cared to participate would pay his own way toward retirement. Under the latter, persons obtain pensions at cut-rate prices because the OASI taxes are mere token payments. Many activities of the Director and of the members of the Bureau staff during the past year have been directed at driving home this major point about H. R. 10 to the members of the medical profession, other professions, the House Ways and Means Committee, its technical staff, and certain segments of the public. The most disappointing feature of this work has been the failure to make it clear to the 32 million pensionless employed and the 11 million self-employed that the American Medical Association is fighting for a reasonable opportunity for them to save for their old age under favorable tax conditions. The Director regrets that in his position he has found no effective way to inform these 43 million—mostly "small" persons—of the efforts the Association is making in their behalf.

The shorter publications of the Bureau are usually multigraphed or mimeographed; they are designated by an "M." M-70 is a reprint of the section of the proceedings of the House of Delegates relating to blood bank matters, December, 1952. M-71, a long editorial, "Three Challenges of the Future," discusses the changing meaning of socialism, the effect of aging on the voting population, and the need for voluntary health insurance to serve an aging population. M-72 concludes that medical debt is currently about 4% or 5% of the total of consumer debt, a percentage far below that suggested in a prominent news weekly of Oct. 17, 1952. M-73, "The Norris Panacea," is a critical analysis of the proposals by Dr. Norris to let businessmen solve the economic problems of medical care. His proposal is a throwback to the majority report of the Committee on the Cost of Medical Care of two decades ago. M-74 is a collection of five papers—by Cooley, Schmidt, Miller, Hayden, and Dickinson—on financing a health program for America, presented at the last panel held by President Truman's Commission on the Health Needs of the Nation. These five papers present abundant evidence that the Commission heard but ignored the recommendations of persons it considered sufficiently well informed on the subject to invite to the panel. The Director in his paper entitled "What We Get For What We Spend For Medical Care" criticized the Commission for placing so much stress on what people spend for medical care without placing equal stress on what they get for what they spend. M-75, "How Far From a Physician?" is a reprint from the Organization Section of The Journal announcing the publication of Bulletin 94A and calling attention to a few of its features. M-76, is a reprint of the section of the Proceedings of the House of Delegates, June, 1953, dealing with blood bank matters. Incorporated into the report of the Committee on Blood to the House of Delegates was a table showing the results of the Bureau's 1952 blood bank survey. In contrast with the two earlier surveys of blood banking in the United States by the Bureau, there will be no separate bulletin on the 1952 survey. Presumably this is the last item in the series, as future publications of this sort probably will be handled by the Secretary of the Committee on Blood. M-77, providing new data for 1952 on personal consumer expenditures for medical care, is another item in the long series on the medical care dollar.

Other Activities

A total of 23 items were published in The Journal, of which nine were book reviews. Four articles or papers were published elsewhere. The Director made 11 speeches during the year, including seven to medical societies; he discussed the fundamental principles of insurance at the 1953 meeting of the Blue Shield Commission.

The I. B. M. section again prepared the tables for the annual hospital survey and the internship and residency survey reported in The Journal by the Council on Medical Education and Hospitals. The section has continued to do the accounting on gifts to the American Medical Education Foundation. Some of this work is done every week. Almost every day work is being done for the Membership and Subscription Department. The I. B. M. system of that department is an outgrowth of the Bureau's I. B. M. section, and the large, expensive machines in the Bureau's section handle all the department's tabulating work. I. B. M. operations for special studies by the Council on National Emergency Medical Service and by the Committee for the Study of Relations Between Osteopathy and Medicine, were performed during the year. I. B. M. services were also rendered, with the approval of the Secretary and General Manager, to Alpha Kappa Kappa medical fraternity, United States Public Health Service, American Nurses' Association, New York Heart Association, Association of American Medical Colleges, Joint Commission on Accreditation of Hospitals, and Commission on Financing Hospital Care.

The Wisconsin section of the I. B. M. deck of punched cards have been reproduced with certain columns left blank. The State Medical Society of Wisconsin will use this deck as a basis for keeping its membership and possibly its Blue Shield records. The Bureau will exchange information by reproducing punched cards for changes, additions, and deaths for the Wisconsin society. If the experiment proves successful and the procedure practical, other state societies will be accommodated.

The I. B. M. operations require the services of well over half of the Bureau staff and approximately half of its budget. The interdepartmental projects have, however, provided a welcome opportunity for close cooperation with other departments.

Report of Bureau of Exhibits

The Scientific Exhibit

DENVER CLINICAL MEETING

There were 71 scientific exhibits at the Denver meeting, originating in 28 cities from coast to coast and from Minnesota to Louisiana. The exhibits were selected for their interest to the physician in general practice and attracted attentive audiences continuously throughout the week.

Special features were very popular. The special exhibit on fractures was conducted by Drs. Gordon M. Morrison, Boston, Ralph G. Carothers, Cincinnati, and Herbert M. Virgin Jr., Miami, assisted by 32 surgeons. It occupied three booths. The special exhibit on artificial respiration was presented by the Council on Physical Medicine and Rehabilitation and the American National Red Cross, under the chairmanship of Dr. Archer S. Gordon, Chicago. Manikin demonstrations on the problems of delivery were carried on at stated intervals by a group of Denver obstetricians. A group of exhibits emphasized practical office procedures in anesthesiology, cardiology, dermatology, endocrinology, gynecology, laboratory work, pediatrics, and proctology. Other exhibits covered many phases of modern medical practice.

The Scientific Exhibit at the Denver meeting was a distinct success, eliciting many laudatory comments. The Clinical Meeting is gradually developing a character of its own, rather than being a small replica of the Annual Meeting. Being held in the smaller cities, it gives an opportunity for many physicians to attend who usually do not go to an Annual Meeting; 98% of the Colorado members registered. All of these spent much time studying the exhibits and watching the demonstrations at Denver. A pattern was set for future scientific exhibits.

Medical motion pictures were shown in an area adjacent to the exhibits, 15 films being presented once each day. A feature was a three dimension color film that attracted large audiences. This program was arranged by the Committee on Medical Motion Pictures.

NEW YORK ANNUAL MEETNG

The Scientific Exhibit, in spite of cramped quarters and difficult access, was visited by most of the 48,000 persons attending the meeting. There were 260 exhibits, selected from more than 500 applications, resulting in material of high caliber and great teaching value.

The special exhibit on fractures, under the guidance of the Fracture Committee, initiated a somewhat different method of presentation in addition to the plaster demonstrations. As in the past, a fine group of demonstrators carried on throughout the week. The special exhibit on fresh pathology attracted large crowds continuously. Dr. Frank B. Queen, Portland, Oregon, and Dr. Milton Helpern, New York, were assisted by an outstanding group of pathologists. The special exhibit on artificial respiration, with Dr. Archer S. Gordon, Chicago, as chairman, was shown for the third time. The New York Police Department, the American National Red Cross, and other groups assisted. The Section on Pediatrics presented an exhibit symposium on the prevention of childhood accidents that had popular appeal.

The 20 sections of the Scientific Assembly arranged groups of exhibits dealing with their respective specialties. Care was taken, however, that each exhibit was broad enough in character to be of interest to physicians in other specialties as well as to those in general practice. The largest group was that of the Section on Internal Medicine, with 23 exhibits selected from 54 applications for space. The smallest group was the Section on Ophthalmology, with 5 exhibits selected from 11 applications. Many excellent exhibits of necessity were omitted because there was not sufficient room on the fourth floor of Grand Central Palace.

The Scientific Exhibit was open for 40 hours during the week, requiring great stamina for those demonstrators who did not have associates to relieve them. In some instances, two or three demonstrators alternated, while in many booths two or more demonstrators were continuously on duty. The program carried the names of 825 participants in the Scientific Exhibit, to which number was added some 500 technicians, nurses, and other assistants who in one way or another took part in the meeting. The medical profession is deeply indebted to all of those persons who contributed so liberally of their time, energy, and knowledge.

The representatives to the Scientific Exhibit, elected by the Sections, gave a great deal of assistance to the Committee. For the first time the Representatives met with the Section Secretaries in the preceding Fall with much mutual benefit. It is the desire of both the Committee on Scientific Exhibit and the Council on Scientific Assembly to coordinate the programs of the two groups as closely as possible.

There were 44 awards for exhibits, consisting of 6 medals, 21 certificates of merit, and 17 honorable mentions. The Committee on Awards consisted of Drs. William B. Condon, Denver, chairman; S. W. Donaldson, Ann Arbor, Mich.; Robert M. Stecher, Cleveland; Ralph M. Tovell, Hartford, Conn., and Robert J. Joplin, Boston.

Motion pictures, arranged by the Committee on Medical Motion Pictures, were shown at the Biltmore Hotel. There were 30 films arranged on a definite schedule, each film being shown at least twice during the week. The attendance was good with the room overflowing in some instances.

Cooperation with Council on Scientific Assembly

Close cooperation has been maintained between the Bureau of Exhibits and the Council on Scientific Assembly. Representatives of each group have attended all meetings of the other group, and much information has been exchanged.

The task of preparing meeting rooms for Sections and for general meetings has been continued with the advice of the Council and the Secretary's office. At the Denver meeting, several rooms were constructed in the exhibit hall and furnished with the necessary appointments. At the New York meeting, rooms were widely scattered, making their upkeep an arduous task.

Association Exhibits

Exhibits depicting the activities, aims, and purposes of the various councils and bureaus of the Association have demonstrated their popularity by demands from many sources. Such exhibits are prepared with the advice and guidance of the departments concerned and are sent to state and county medical societies or to groups approved by such societies.

Association exhibits fall into two groups: (1) medical exhibits for medical societies and other scientific groups, and (2) health exhibits for fairs, expositions and other public gatherings. There are now 50 subjects covered by Association exhibits, 12 of which have been added during the last year.

Several of the exhibits are in duplicate to satisfy the demand. The most popular subject continues to be "Testing the Drinking Driver," a joint exhibit of the Committee on Medicolegal Problems of the Association and the Committee on Chemical Tests of the National Safety Council. Some lightweight exhibits have been prepared during the year that can be shipped long distances at nominal costs. These are used by the Woman's Auxiliary, Parent-Teacher Associations, and other groups with a relatively small attendance. Association exhibits were scheduled for showing during the calendar year in 31 states and in Canada. The exhibits were used by 30 state medical societies and 29 county medical societies. All groups and agencies combined used the exhibits 206 times for a total number of 591 showing days. Other new exhibits have been designed and plans drawn for their construction.

Museums

The House of Delegates adopted a resolution in 1940 endorsing health museums and instructing "the Board of Trustees, officers and employees to give all possible support to such museums, wherever they may be developed in conjunction with local medical organizations." Such museums are of two types: The independent health museum as found in Cleveland and Dallas, and the science museum, or natural history museum, which devotes a part of its space to health exhibits. There are a considerable number of the latter, the most notable example being the Museum of Science and Industry in Chicago. Exhibits installed some years ago are still being shown at the health museums in Cleveland and Dallas, the Museum of Science and Industry in Chicago, and the Army Medical Museum in Washington. Conferences have been held concerning health exhibits at the Smithsonian Institution in Washington and elsewhere. The opportunity for health education which such institutions offer is almost beyond conception. Millions of visitors come in an inquiring frame of mind and spend long hours of studious observation. The museums of the country are recommended to the county medical societies for health education at a very small cost per capita.

Committee on Medical Motion Pictures

The demand for motion pictures has continued to increase. Numerous conferences have been held with members of the headquarters staff as well as with outside agencies on matters pertaining to this method of instruction.

Film Library.—Nineteen new films were added to the motion picture film library. A revised catalog listing a total of 92 subjects was prepared and distributed to county and state medical societies and to medical schools. Shipments of 2,205 films were made to various medical groups. Eighty-seven per cent of all medical schools in the United States used these films at some time during the year. Service charges totaled approximately $6,750.

Film Reviews.—New films have been reviewed by competent specialists, and such reviews have been published in The Journal. A supplement to the second revised edition of the Booklet of Reviews was published in January, 1953, including all reviews appearing in The Journal during 1952. A cumulative index, covering all reviews published, was prepared and copies were sent to each state medical society and medical school. Copies were also made available to the county medical societies.

Films for Television.—A supplement to the List of Health Education Motion Pictures Cleared for Use on Television, listing 39 films, was prepared and made available on April 1, 1953.

Annual and Clinical Meetings.—The Committee on Medical Motion Pictures was responsible for the motion picture program at the 1953 New York Meeting, with 30 films shown on a definite schedule, and at the Denver Meeting, with 14 films. All films were previewed by competent authorities before they were put on the program.

Hospital Survey.—At the request of the Committee, several questions concerning the availability and use of medical motion pictures and projection equipment were included in the 1952 Hospital Survey of the Council on Medical Education and Hospitals. An analysis of the results indicates that most hospitals are now equipped with 16 mm. motion picture projection equipment; those lacking such equipment usually fall into the group having less than 100 beds. A total of 813 hospitals indicated that motion pictures were used "often" in medical staff meetings; 3,081 reported an occasional use; 1,899 did not employ this method; and 872 did not reply. In response to the question regarding the use of films now in comparison with five years ago, 3,109 hospitals stated that motion pictures are now being used more extensively, 79 indicated less frequent use, 1,093 reported no change, and 2,384 did not respond.

Special Projects.—The Secretary of the Committee served as Honorary Chairman of the Section on Audio-Visual Teaching of the 10th National Assembly of Surgeons, Mexico City, Dec. 9 to 15, 1952. A paper was presented on the use of motion pictures and television in medical education, and 15 medical motion pictures from the United States were shown on the official motion picture program. At the request of the Chief of Field Party of the Institute of Inter-American Affairs, the secretary visited the new medical school at Vera Cruz where the subject of medical motion pictures was discussed with the dean and members of the faculty.

The Secretary of the Committee attended the first World Conference on Medical Education in London and addressed the Section on Techniques and Methods of Medical Education on the subject, "The Effectiveness and Use of Motion Pictures in Medical Teaching." Other meetings which he addressed are as follows:

Edinburgh Film Festival, Edinburgh, Scotland.
Medical Section of the Royal Photographic Society, London.
Motion Picture Committee of the British Medical Association, London.
Scientific Film Association, London.

The Committee prepared extracts of the State Department Catalog of Films Available for Overseas Use covering the subjects of health films and medical films. The extracts were made available to interested medical groups in Great Britain.

A film program was arranged for the thirteenth Annual Congress on Industrial Health, as well as for the third annual convention of the Student American Medical Association. Among the films shown at the latter meeting was a première of "El Nuevo Medico" (The New Doctor) produced in Mexico. This film program was so well attended that plans are being made to continue it at the next S. A. M. A. convention.

MISCELLANEOUS ACTIVITIES

Numerous miscellaneous activities have been carried on by members of the staff. Lectures, conferences, articles and books for publication, and book reviews have been undertaken as time has permitted. As formerly, the Bureau of Exhibits is integrated into all of the activities of the Association.

Report of Council on Rural Health

The Council on Rural Health has had the busiest and most productive year of its existence. It has held three meetings of the entire Council and five meetings of the executive committee in order to meet contemporary needs, to assay particular situations, and to plan for future activities. In a nationwide effort that has developed out of eight years of experience, it has become increasingly important that the leadership the American Medical Association has given to such a multiphasic program be kept alert and ahead of lay organizations that are interested and active in this field.

The Council has continued to enjoy the cooperation and support of its Advisory Committee members and their parent organizations. There are many striking illustrations across the nation, showing the local application of suggestions made at National Conferences on Rural Health, or in conferences held with the constituent organizations of the members who make up the Advisory Committee. Where a few years back the National Conference on Rural Health was one of the chief activities of the Council, there are now added many state rural health conferences and scores of local activities in strictly rural communities. This has come out of lay organizations learning that organized medicine is sincere in its intent to assist them with their health, hospital, and medical care problems. It also comes from the fact that physicians are learning that lay leadership sincerely desires their advice and guidance in these matters. It is a mutual confidence and respect that is growing out of teamwork.

In addition to demands on the Chairman's time in the routine affairs of the Council, he has accepted requests from many state and local groups for public appearances to discuss the rural health movement.

After numerous requests from many lay organizations and medical leaders for some medium of exchange for ideas and news on rural health activities, the Council has started publication of a newsletter called "Parade of Progress." One issue of the three proposed for 1953 has been distributed, and the other two will be sent out in the last quarter of the year. The newsletter is published only as enough worth while items are accumulated to keep it interesting and effective. The first issue has met with wide approval.

Two more state medical associations have appointed rural health committees this year, making a total of 45 states that have a committee on rural health or some similar committee with rural health as a responsibility. Arizona, Rhode Island, and Massachusetts do not have such a committee. In most of the states the committees are active, with many of them showing outstanding accomplishments.

Statewide one and two day rural health conferences have been held in 15 states in which the state medical association's Committee on Rural Health and its executive staff took the leadership, getting the cooperation of lay groups as co-sponsors of each of the events. These states are North Carolina, Kentucky, Michigan, Arkansas, Oklahoma, Montana, Washington, Louisiana, Missouri, Texas, Ohio, Oregon, Indiana, Wisconsin and Colorado.

Attendance at these meetings has run from 150 to 700. At most of them there is good representation of actual rural leadership. It has been observed that the balance between farm leadership, the medical profession and lay professional workers, such as health department and extension service employees, has been good. The Council would like to see more physician participation in some of the conferences, but on the whole it has been good.

In 12 other states, the Committee on Rural Health of the state medical association is either participating in the work of the state rural health council or has invited lay farm groups to meet and work with them in conferences of various kinds during the year. In several of these, this activity has been very similar to a state rural health conference except on a smaller scale. They have been exploratory or planning in nature, and will lead to broader and more intensive activities. These states are Pennsylvania, Illinois, North Dakota, Virginia, Mississippi, Wyoming, South Carolina, Minnesota, Idaho, Tennessee, Iowa, and California.

In each of the other 18 states, the rural health committees have carried many different types of activities designed to bring about both better health and medical care conditions in the states and a better understanding with the rural lay public. In South Dakota, for example, a pamphlet showing medical service areas was prepared by the rural health committee about three years ago. The pamphlet has now been revised and shows the results of the physician placement program. Assistance has been given local communities not only in obtaining physicians but also in building hospitals to meet local requirements.

It is not possible to cite all the types of activities being carried on in the states, counties, and communities. A few illustrations will perhaps suffice. It will be noted that these illustrations differ from state to state; they are adapted to fit the peculiar needs of the states, yet all are pointed to the same goal, "to help rural people help themselves to better health." It is the conviction of the Council that herein lies the strength of the rural health program. No attempt is made at uniformity because needs vary from community to community throughout the country.

In the midwestern region—Michigan, Ohio, Illinois, Indiana, and Missouri—the procurement, training, and placement of rural physicians has been a major and common project. Through scholarships for medical students, lecture courses on rural practice in the medical schools, and actual assistance in the placement of physicians in rural areas, the situation is steadily improving.

In the North Atlantic area, composed of the states of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New Jersey, New York, Delaware, and Pennsylvania, the medical care and hospital problems of rural communities are not so acute. However, the gaps are rapidly being filled and more attention is now being given to prepaid medical care, problems of rural sanitation, and similar activities.

With the rapidly growing population which is purchasing small tracts of land in the open country on which homes are being built, many health problems in connection with water supply, sewage disposal, and other sanitary measures are being created. It is felt that these have to be taken care of well in advance to avoid difficulties later.

In the Central Atlantic area, composed of the states of Maryland, Virginia, West Virginia, North Carolina, South Carolina, Kentucky, and Tennessee, the program has varied from an intensive county study and analysis, by the Rural Health Committee of the North Carolina medical association, and the concentrated physician placement program of the Virginia Council on Health and Medical Care, to the beginning efforts and conferences of the Tennessee and South Carolina medical associations. Progress is good in the region. Kentucky is still developing its outstanding medical scholarship and placement programs and is extending its state rural health conference back to the rural community.

In the Southeastern region composed of Arkansas, Louisiana, Mississippi, Alabama, Georgia, and Florida, the states have widely differing programs. All states have active rural health committees and organizational leadership in each county of the state.

In the Southern Great Plains region, composed of Texas, Oklahoma, and Kansas, the rural health program has stepped up in intensity. The Texas Medical Association's Rural Health Committee completed a study of physician location and population and has presented it to the Texas Rural Health Council. The Committee has developed preceptorship programs with the medical schools, similar to that in Kansas, and has developed an orientation day similar to that of Nebraska for senior medical students with two of the state's medical schools. Oklahoma has held its first rural health conference, with gratifying response, and has established excellent public relations with most of the rural organizations.

In the North Central Great Plains region, composed of North Dakota, South Dakota, Minnesota, Wisconsin, Iowa, and Nebraska, an excellent but varied program in rural health has been developed. In most of this region there is a rather difficult situation with certain radical, so-called liberal urban and rural groups. By considerable patience and courage the medical leadership has succeeded in building realistic programs to meet the needs of the people.

In the Rocky Mountain region, composed of New Mexico, Colorado, Wyoming, Utah, and Montana, most gratifying progress has been made in rural health programs. Each state in the region has activities going on in the broad fields of rural health, medical care, and safety. Problems such as training nurses, strengthening the medical education program, physician placement, and prepayment insurance are receiving special attention.

In the Pacific Northwest region, composed of Washington, Oregon, and Idaho, two excellent state rural health conferences have been held, Oregon holding its third and Washington its first. The working relationship between the medical profession and the lay organizations in these states is exceptionally good.

In the Pacific Coast region, composed of California, Arizona, and Nevada, the problem of migrant and "fringe area" agricultural workers continues to be a major problem. California has made splendid progress on this and many other problems.

Most of the activities mentioned in the foregoing have come about as a result of the eighth National Conference on Rural Health. Many rural leaders point out that they obtained their original inspiration and information from one or more of these conferences. In the opinion of the Council this has and continues to be an important function. It still continues its important function in finding areas of agreement, out of which state and local groups may begin their own activities, and which the Council follows up throughout the year in numerous contacts.

In addition to the regular routine activities of the Council office, there continues to be maintained a close working relationship with all state medical societies, state rural health committees, or committees handling rural health matters, as well as national organizations including farm groups. This includes attendance at national meetings of farm organizations, state rural health meetings, and special assignments delegated by the Chairman and Council members. It also includes personal contacts with leaders of women's organizations, suggestions and assistance for the formation of rural health programs, and program planning for and cooperation with all interested lay groups.

In connection with the eighth National Conference on Rural Health at Roanoke, Va., Feb. 26, 27, and 28, a preconvention flier was prepared and 2,000 copies were sent to both professional and lay leaders. This was in addition to the approximately 4,000 personalized invitations and programs that went to the entire mailing list, containing detailed information on the National Rural Health Conference. Numerous items of information have been collected and distributed to interested groups during the year, and approximately 19,000 pieces of literature of various types and descriptions dealing with rural health activities have been sent out from this office. In addition there have been prepared and distributed approximately 4,000 copies of the digest of the eighth National Conference on Rural Health.

After several sites for the 1955 Conference were investigated, Milwaukee, Wis., was selected as the location of the tenth National Conference on Rural Health and the dates chosen are Feb. 24, 25, and 26. In all probability the 1956 Conference will be held some place along the West Coast or in that vicinity.

The eighth National Conference on Rural Health in a number of ways was the best conference yet held. It had the largest registered attendance, and there was more active interest and participation. Moreover, it was given the widest coverage by the press, radio, and television services than any other of the conferences. The Department of Public Relations has always given their wholehearted support, and this was especially true in this case. The Public Relations Department contacted the press, radio, and television services more than two months in advance of the meeting and invited them to sit with the Executive Committee and staff of the Council at a meeting in Roanoke early in January. Two items on this conference program had an unusually gratifying reception, both at the time of the conference and since. The paper given by the Chairman entitled "Looking Back to Look Ahead," in which he reviewed past activities and outlined future hopes of the Council, has been in wide demand by groups all over the nation. The paper by the Vice Chairman of the Council on prepayment insurance has likewise been popular and in heavy demand.

The Council is especially fortunate in having the farm organization leadership serve as an Advisory Committee. The past pleasant association with this group, representing the American Farm Bureau Federation with its more than 1,500,000 members, the National Grange with its approximately 800,000 members, the National Milk Producers Federation with its hundreds of associated groups, the Agricultural Extension Service of the Land Grant Colleges and Universities with its staff in every agricultural county in the nation, the Agricultural Editors Association with the millions of farm readers, and the Farm Foundation with its wide recognition in agricultural circles, has been continued during the year. In the past the members of this Advisory Committee have advised the Council on the preparation of the National Conference programs and on current problems. This year a wider use of their experience and knowledge of rural conditions is being made. Each of the representatives was interviewed in the month of August prior to a two-day meeting on Sept. 11 and 12, at which time the developments of the past eight years and the changing agricultural economic situation were discussed. The Council is making a continuing and comprehensive reappraisal of its program.

For the purpose of exchanging ideas, a special meeting has been arranged with the Board of Directors of the American Farm Bureau and the Extension Committee on Organization and Policy. It is hoped that other organizations can be similarly contacted next year.

The Field Director has maintained constant liaison with as many of the rural organizations of the nation as has been possible. Of necessity some of this work had to be done by correspondence rather than in personal contacts. In addition to the formal meetings attended and addresses given, an occasional letter or personal contact is made to keep these groups advised on the many activities of the American Medical Association, the state medical association, county medical societies, and individual physicians. The Field Director has studied the whole program of the American Medical Association and worked within the framework of its policies. He has stayed close to members of the Council and especially the Chairman, with whom frequent consultations have been held. He has also drawn freely on the management and resources of the Association, and the various bureaus and councils have been most helpful.

Report of State Journal Advertising Bureau

The State Journal Advertising Bureau, operating under the auspices of the Board of Trustees, functions in behalf of 34 state medical journals, official publications of 39 state medical societies.

The purpose of the Bureau is to render assistance to its member journals by securing advertising space sales and servicing accounts. A monthly bulletin is issued which offers helpful suggestions on advertising make-up, comments on economic trends, and a listing of products currently accepted by the Councils on Pharmacy and Chemistry, Foods and Nutrition, and Physical Medicine and Rehabilitation, and the Committee on Cosmetics.

The Bureau is governed by the Advisory Committee, which is composed of Drs. Stanley B. Weld, Connecticut, Chairman; Douglas W. Macomber, Colorado; L. Fernald Foster, Michigan; Julian P. Price, South Carolina; and Walter E. Vest, West Virginia. Mr. Alfred J. Jackson, Director of the Bureau, serves as Secretary of the Advisory Committee. Ex officio members are Drs. George F. Lull, Secretary and General Manager, Austin Smith, Chairman of the Advertising Committee, and Robert T. Stormont, Secretary of the Council on Pharmacy and Chemistry, of the American Medical Association.

The following official 34 state publications are members of the State Journal Advertising Bureau at the present time:

Journal of the Medical Association of the State of Alabama
Arizona Medicine
Journal of the Arkansas Medical Society
Connecticut State Medical Journal
Delaware State Medical Journal
Medical Annals of the District of Columbia
Journal of the Florida Medical Association
Journal of the Medical Association of Georgia
Hawaii Medical Journal
Journal of the Indiana State Medical Association
Journal of the Iowa State Medical Society
Journal of the Kansas Medical Society
Journal of the Kentucky State Medical Association
Journal of the Louisiana State Medical Society
Journal of the Maine Medical Association
Maryland Medical Journal
Journal of the Michigan State Medical Society
Minnesota Medicine
Missouri Medicine
Nebraska State Medical Journal
New England Journal of Medicine (Massachusetts & New Hampshire)
Journal of the Medical Society of New Jersey
North Carolina Medical Journal
Ohio State Medical Journal
Journal of the Oklahoma State Medical Association
Pennsylvania Medical Journal
Rocky Mountain Medical Journal (Colorado, Montana, New Mexico, Utah and Wyoming)
Journal of the South Carolina Medical Association
South Dakota Journal of Medicine
Journal of the Tennessee State Medical Association
Texas State Journal of Medicine
Virginia Medical Monthly
West Virginia Medical Journal
Wisconsin Medical Journal

Council acceptance of new products opens up an avenue of further advertising prospects, since all of the member journals follow standards of advertising adopted for the publications of the American Medical Association. It is therefore hoped to maintain present sales in subsequent years and even to increase them. The Bureau is not only self-sustaining but also a revenue producer for the state journals. During the past eight years the net sales have exceeded $5,049,000. This amount, less the Bureau's operating costs of about 6%, has been transmitted to the journal members.

Today's Health

The period covered in this report is from Sept. 1, 1952, through Aug. 31, 1953. It has been a year of testing and challenge for *Today's Health.*

After many years of alternating between small profits and equally small deficits, the magazine began in 1947 to enter upon an era of unfavorable conditions. The end of World War II brought about the discontinuance of high wartime taxation on corporations. This in turn resulted in the loss of so-called institutional advertising, the cost of which was deductible from corporation taxes. *Today's Health* lost 21 large accounts of this character. Other unfavorable factors were steadily rising wage and material costs, which have practically doubled production cost of the magazine. Postage rates also were increased. The effects of inflation on families of moderate means, which constitute the bulk of the subscribers, caused the curtailment of magazine subscriptions. In such cutbacks, specialty magazines like *Today's Health* are among the first casualties. Families tend to keep a weekly fiction magazine, a weekly news magazine, a household magazine, and magazines of religious or organizational character in which they have a special interest.

In 1949 when the present editor took charge, the percentage of subscribers renewing on expiration was exceedingly low.

Of new subscribers procured in a given year, only 10% were left at the end of three years. The average renewal percentage at the expiration of an initial trial subscription was in the neighborhood of 33%. This percentage has risen to 47% at the end of the year covered by this report. Indications are that it will exceed 50% during the next year.

The change of name from *Hygeia* to *Today's Health* brought a small amount of adverse criticism, but most of this has now disappeared and the new name is firmly established, together with a new personality, format, and art work.

Financially the magazine had two years immediately preceding the one covered by this report in which the net cost to the Association was relatively large. Including approximately $59,000 of bookkeeping debits, which do not represent cash outlay, the net cost for the last preceding year was $210,000, representing a net cash outlay above receipts of roughly $150,000. This large amount has naturally raised the question as to whether the Association is getting its money's worth in health education and community relations out of the magazine.

The extensive use of *Today's Health* in schools and public libraries and in the offices of physicians and dentists multiplies its readership far beyond its circulation. A conservative estimate is that there are between two and three million readers per issue exclusive of the secondary audience reached through reprinting of articles in other magazines. The estimated cost per reader per month is a fraction of one cent. From another viewpoint the net cost of $150,000 is bringing the Association a gross operation worth approximately $700,000 or almost 5 to 1 on a dollar basis.

An index of the influence wielded by *Today's Health* is the demand for reprints. With *Reader's Digest* heading the list in point of circulation, 86 magazines have reprinted 162 articles from *Today's Health* in the year covered by this report. Their combined circulation is estimated to be in excess of 14 million readers.

Net paid circulation has remained at a high level by reason of previous momentum plus some significant factors reflecting on improved reader acceptance. Agency sales have risen sharply, which means that the magazine virtually sells itself from catalog listings and procurement costs nothing. State and local medical societies and the Woman's Auxiliary are taking a renewed interest in the magazine. Large industrial orders have increased. In summary, the magazine is at a point where there is every reason to believe that the corner has been turned and that it is on the upward path. Indications in September are that the net cost of *Today's Health* during the fiscal year 1953 will be under $150,000, including all bookkeeping charges.

The main editorial criterion of where *Today's Health* stands today is something that may seem intangible but is not actually so—personality. That was something the old *Hygeia* had, indelibly. It seemed, however, that the character of *Hygeia* was somewhat limited, perhaps behind the times. It seemed urgent that a personality in step with today and capable of appealing to wide groups of today's readers should be developed. It required the development of a sufficient backlog of good manuscripts to allow some choice and some flexibility. It involved endless, detailed changes and eternal vigilance and the development in the staff of a clear sense of direction. The result is that in the last year or so *Today's Health* actually has begun to shape up as a new personality, and one that seems to appeal to a wide range of readers.

Studying the magazine itself provides perhaps the best evidence, but aside from that a few concrete indications may be mentioned. Perhaps most impressive are the rising renewal rate and the slow, but apparently solid, increase in advertising. Ranking next was the final report on the study by the Eastman Research Organization, which states in the opening paragraph that *Today's Health* "again shows gratifying and quite undeniable evidence of healthy progress."

The art director was one of 16 distinguished artists chosen to plan the 1953 Magazine Show of the American Institute of Graphic Arts. In 1951 *Today's Health* was entered in this show, the most important of its kind, and took two awards.

An article on "How to Read Science Stories," by the assistant managing editor drew the attention of the Science Committee participating in a four-year project of the American Council of Education. Nineteen institutions are collaborating in this study, in which an objective of the Science Committee is to foster the development of courses for general students that provide not merely factual information "but rather an understanding of what science is and how it operates." One project of that committee is a Handbook for College Teachers, which will devote a chapter to the evaluation of popular articles. The committee requested permission to reproduce the article mentioned.

CIRCULATION

The average net paid circulation for the first six months of 1953 was 260,601, which was a slight gain over the net paid circulation for the last six months of 1952. The average net paid circulation for the last six months of 1953 is not expected to show a further increase because of a limitation on the expenditures for new orders to replace subscriptions expiring during the latter half of the year. A gradual increase in the renewal percentage reflects a more favorable acceptance of the magazine, better new subscriber selection, and a continued improvement of renewal solicitation material.

A survey of the mailing list for the May, 1953, issue indicated the following breakdown in types of subscribers:

Subscriber Classifications	Percentage of Total Subscriptions
Lay Subscribers	69.0
Nurses	2.0
Physicians	10.0
Dentists	3.0
Hospitals	0.5
Schools, Teachers	9.0
Public Libraries	1.5
Clergymen	0.5
Miscellaneous	4.5

All classifications showed a moderate gain during the past fiscal year, proportionate to the general increase in paid circulation. New and renewal orders from physicians were stimulated by the use of an attractive folder sent to each member of the American Medical Association with his 1953 membership card.

The use of the magazine in high schools and colleges was reflected by a gratifying increase in the number of copies purchased. An average of 4,556 copies per month were used during the past school year as a supplementary text book, as compared with 2,367 copies per month during the previous school year. These copies are supplied at a special bulk rate for quantity orders, and the teacher is furnished a list of questions and answers based on the articles in each issue. In the year ending June 30, 1953, 45,561 copies were ordered as compared with 23,669 copies in the previous period.

The Woman's Auxiliary to the American Medical Association again worked closely with the Circulation Division in promoting a wider distribution of *Today's Health.* A monthly bulletin called "Tips 'N Topics," plus promotional material, furnished the regional, state, and local officers with helpful aids in carrying on this work. In addition, the auxiliaries were instrumental in obtaining renewals of gift subscriptions from 21 constituent state medical associations for legislators, public officials, and schools in their respective communities. This public relations endeavor supplied copies of the magazine to United States senators and representatives, state legislators, judges, public health officials, school officials, labor and civic leaders, and public and school libraries. Under the capable direction of the national, regional, state, and county *Today's Health* chairmen, the auxiliaries accounted for 33,034 new and renewal subscriptions. This is an increase of 6,832 subscriptions over the previous year and is the highest net gain in any one year of the 17 years of the Auxiliary program.

Promotion efforts continue the increase in the use of *Today's Health* in industrial health programs. Group orders ranging from 10 to 1,300 copies were received from three pharmaceutical firms, the faculties of two large universities, several public utility companies, six area offices of Blue Cross and Blue Shield, seven large industrial firms, and several insurance companies. This use of the magazine as a health education medium in the industrial field is growing, and has led to a wider recognition of the health education value of the magazine by the general public.

ADVERTISING

From an advertising standpoint, *Today's Health* has enjoyed a very successful year. It is interesting to note that 1953 is the first year since 1947 that *Today's Health* has shown an increase in both advertising pages and dollar volume. The chief reasons for this "about-face" are greater acceptance of the magazine by both the reader and the advertiser, increased circulation, a coordinated advertising sales approach, and more adequate sales representation in the field. These factors have made it possible to establish 67 new advertising accounts in the first nine months of 1953. This compares to a total of only 52 new accounts established in 1952.

Advertising promotion activities, including direct mail and trade paper advertising, have paid off very well this year. Much of the work being done today is aimed at renewing contracts for next year, and prospects at the moment are excellent, anticipating at least a 15% increase in page and dollar volume in 1954. The newly established feature "Helpful Hints for Better Living" has taken hold and in the first 12 months of publication has accounted for nearly 60,000 inquiries. This feature not only gives *Today's Health* readers an opportunity to gain more information about advertised products, but it enhances the value of display advertising.

Report of Bureau of Health Education

The Bureau of Health Education has continued its work along previously established lines during the year ending Aug. 31, 1953. Correspondence from nonmedical inquirers asking health questions occupies the full time of the Associate Director, Dr. William W. Bolton, and of two stenographers, plus fractions of the time of the remainder of the Bureau staff. Consultants in the medical and allied sciences outside of the American Medical Association headquarters are called on frequently. Published questions selected from this correspondence continue to be among the most popular features of *Today's Health* as indicated by readership surveys.

The Bureau has been concerned with the relationship of radio to television. The phenomenal growth of the latter medium to an estimated 26 million or more receiving sets in operation as of August, 1953, together with the opening of numerous new television transmitters, has raised the question of whether too much attention is being paid to radio. There has been no question that too little attention has hitherto been paid to television.

At the beginning of the year the decision was made to continue with a radio broadcasting program consisting of four series of electrical transcriptions for local use plus one series of six nationwide network radiocasts in the spring. The television budget was applied to the production of six films of five minute length. In conjunction with the Department of Public Relations and the Committee on Medical Motion Pictures, a full length major television film was produced.

Dr. D. A. Dukelow continued his field study of preventive medicine and health teaching in medical schools through personal consultation with professors of preventive medicine; a preliminary report on this project will soon be forthcoming.

Preparations were begun for the Fourth Conference on Physicians and Schools, a biennial event initiated in 1947. This is scheduled for Sept. 30 to Oct. 2, 1953, which is just outside the scope of this report and will be incorporated in the report for 1954. Advance registrations point to an exceptionally successful conference.

The usual variety of committee and liaison work is carried on in cooperation with other agencies, often in conjunction with other bureaus and departments at American Medical Association headquarters. The Joint Committee with the National Education Association has completed its new book, "Health Service in Schools," a companion volume to "Health Education." The new book will be available for distribution before the end of September, 1953. The Bureau continues to work closely with the staff of *Today's Health*, each supplementing the other until the line of demarcation is indistinguishable.

The telecast, "Medicine and the Mighty Atom," made by the Bureau in conjunction with the National Broadcasting Company in the fall of 1952 was awarded "Special Mention" by the Institute for Education in Radio and Television held annually by Ohio State University. "Special Mention" is a citation awarded only occasionally for programs of special merit as distinguished from ordinary first awards and honorable mentions.

QUESTIONS AND ANSWERS

Communications received from lay correspondents desiring health education information totaled 13,978 for the period from Sept. 1, 1952, to Aug. 31, 1953, representing an appreciable increase. Certain special factors were responsible for the rise. A five-minute television program on weight reduction, presented early in 1953 over the NBC network, produced 882 requests for advice and literature, and several articles on plastic surgery that appeared in various weekly magazines were responsible for 657 inquiries.

As in previous years, correspondence was screened daily by a physician in order to expedite handling of the material. In most instances, literature prepared by the Bureau was sent with a personal reply. In addition to receiving Bureau material, many correspondents were assisted in their search for information by being referred to one or more of the 27 national organizations listed by the Bureau as having a special interest in various diseases and known to distribute literature. Despite the upswing of interest in obesity control and plastic surgery, the highest total of inquiries related to matters of sex education, the figure being 935.

Special free material was mailed to 1,710 persons, most of these being school teachers. In addition, requests for literature dealing with specific disorders were handled, plus 2,000 requests for Bureau catalogs. There was an increase in letters referred from various health museums.

From the replies prepared, topics suitable for publication in the "That's a Good Question" department of *Today's Health* were selected. For part of the year, a separate column containing inquiries and answers on care of children was published, and the same source was utilized in selection of material. This has been merged with the section containing general questions.

LOAN COLLECTIONS

During the year, 70 requests were received for Bureau of Health Education material that could be utilized by professional workers in the preparation of talks to be given before lay groups on medical subjects. This represented a slight decrease from the total for the previous year. Interest was rather widely diversified, 33 topics being included, with no marked preponderance in any area. The greatest number of requests were for material on the general subject of medical advances, sex education, and cancer. Although the year revealed extremely great general interest in the problem of obesity and its correction, only one loan collection for preparation of a talk on this subject was requested. Other topics for which more than single requests were received included child health, communicable disease, heart disease, infantile paralysis, mental hygiene, and narcotics.

NEW ELECTRICAL TRANSCRIPTIONS

The following new radio transcription series has been prepared: *(a)* "Chats with the Champs" features interviews with top flight sports figures, many of whom were on-the-spot interviews recorded in Helsinki, Finland, during the 1952 Olympic Games.

(*b*) "Heart of America" presents fascinating case reports from 13 outstanding cardiologists, dramatized by top radio and television actors. These programs are scientifically accurate portrayals of problems facing the patient with heart disease. The series was produced under the supervision of the American Heart Association and the Bureau of Health Education.

(*c*) "Help Yourself to Health" is a documentary series relating the problems facing rural communities and towns in establishing their own health facilities. The series consists largely of true stories about small American communities that have successfully solved their health problems through local initiative and effort. The verbatim comments used in the transcriptions were tape-recorded at the National Conference on Rural Health held in Denver.

(*d*) "June, July and August" is a dramatization with the Holloway family offering health hints and advice for summertime "nuisances," such as hay fever and summer insects, that take the fun out of outdoor activities. The dramatic presentations are followed by a discussion of summer health problems by the Director of the Bureau of Health Education.

(*e*) "Yours for Health" consists of dramatized stories of 13 major health problems and how the American Medical Association has helped to solve them. The series shows how the work of various Association councils and committees has contributed to better health for the American people.

The five series described above were prepared and released prior to Aug. 31, 1953. In addition, the following series has been prepared for release on Sept. 15, 1953: "Medicine Fights the Killer." The theme of this new series is concerned with what medicine is doing to overcome the principal causes of death in the world today. A second series, "Child Care and Guidance," is being prepared for release in December, 1953.

Network Radio

"Medicine USA" is a dramatized health education series of six half-hour programs concerning fields of medicine in which great strides have been made in recent years. Personalities such as Helen Hayes, Pat O'Brien, Claude Raines, and Kim Hunter starred in the series, which was presented by the American Medical Association in cooperation with the National Broadcasting Company.

Contrary to 1952 experience, when the network radiocast with Charles Laughton attracted widespread attention and much favorable publicity, this series appeared to make little impression. This was not a matter of quality nor of the theatrical stars employed. It now appears to be a reflection of diminished interest in radio network broadcasts. Local radio, on the contrary, continues to give satisfactory results.

Television

A 26 week series of five minute television programs called "MD," featuring helpful health advice, was produced by F. William Hart in cooperation with the American Medical Association to be presented as a portion of the Dave Garroway "Today" show over the NBC network. E. R. Squibb & Sons sponsored the series.

"What to Do" is a series of six five-minute films starring Nancy Craig, American Broadcasting Company woman commentator, who shows "what to do" in home emergencies.

"Operation Herbert" is a half-hour film dramatizing the cost of medical care in a comparison of cost in 1937 and 1953, based on the consumer's price index prepared by the United States Department of Labor.

The two films are available to the county medical societies without charge and may be obtained on a loan basis in the same way in which electrical transcriptions are obtained.

In addition to the above films for television, the Bureau of Health Education, in cooperation with the Smith, Kline and French Laboratories, telecast four live shows, two each from Denver and New York City, under the title "March of Medicine." The distribution of the Television Handbook and prepared television scripts is continuing and has rapidly expanded in recent months.

Radio and Television from Clinical and Annual Meetings

Radio and television service other than scientific telecasting in color in connection with the Denver Clinical Meeting and the New York Annual Meeting were handled, as usual, by the Bureau of Health Education. At both meetings, in many instances the materials were used by well-known broadcasters and telecasters on established programs with wide and regular listening audiences.

DENVER CLINICAL MEETING

Both the Denver broadcasters and the networks were most cooperative in offering their services to tell the public about the Clinical Meeting. Special interviews with various authorities were recorded during the course of the convention for broadcast on outstanding women's programs over the nation. The most-broadcast celebrity was Dr. John Maston Travis of Jacksonville, Texas, sixth "General Practitioner of the Year."

A special broadcast under the title "Today in Medicine" over station KOA outlined the scientific advances presented to physicians attending the Clinical Meeting. The NBC network broadcast a panel discussion on "Behavior Problems in Children."

NEW YORK ANNUAL MEETING

The listing of actual broadcasts scheduled during the course of the New York Meeting does not begin to cover the activities of that meeting, from which there was more broadcasting than at any other meeting in the recollection of the Bureau staff. A total of 93 news editors, program directors, and commentators were furnished with daily releases covering every aspect of the meeting and the papers presented. The releases were furnished by the Public Relations Department, and the Bureau staff saw to it that they were received by the radio broadcasters at the same time the same news would be available to the press correspondents. This was a service deeply appreciated and widely used.

This office also handled television press conferences on a special events basis. The first of these was a preview of exhibits late Sunday afternoon, when the news services were admitted with cameras to take film. Throughout the week the staff always was available to escort the various television men and news services. The Columbia Broadcasting System, Fox-Movietone, Metro-Goldwyn-Mayer, and Telenews took extensive advantage of this privilege.

Television coverage was also secured on the appearance of Mrs. Oveta Culp Hobby in the House of Delegates. Several of the radio and television news services carried the interview with her and greetings from Dr. Louis H. Bauer and Dr. Edward J. McCormick.

This year the Voice of America made particular request for interviews with representatives of foreign nations attending the convention. They furnished the interviewers, and the recordings were made from the headquarters suite for broadcasting back to individual countries. Several of these were 30 minutes in length. All were on the subject of the visiting doctor's impressions and experiences in attending the annual meeting and his observances of medical practices in this country.

Special Broadcasts

The Bureau was invited to handle radio coverage for the Annual Congress on Industrial Health, held at the Drake Hotel, Chicago, Jan. 20 to 22, 1953. Seven visiting medical leaders participated in a radio roundtable discussion, one radio interview, and three television shows.

The Bureau was invited to handle radio coverage for the Annual Congress on Medical Education and Licensure, held at the Palmer House, Chicago, Feb. 8 to 10, 1953. Six visiting medical leaders participated in three radio interviews and three television shows.

LOCAL BROADCASTS

Ten local radio programs, including two network programs and four television broadcasts including two network programs, were given by the staff of the Bureau and others in connection with meetings they were attending in other cities and in Chicago.

HEALTH AND FITNESS DIVISION

The Health and Fitness Consultants provide consultation on the public health and education aspects of school health to state and local medical societies and voluntary and governmental agencies in education and public health. The consultive team, consisting of a physician certified in preventive medicine and public health and an educator trained and experienced in health and physical education, has aided materially in making the Association's counsel on the administrative and interprofessional problems in school health acceptable to all of the professional interests involved.

The Fourth National Conference on Physicians and Schools to be held at the Hotel Moraine, Highland Park, Ill., Sept. 30 to Oct. 2, 1953, was organized and all but the final arrangements made during this year. Invitations to be represented were sent to all state and territorial medical associations, health departments, and education departments, and the principal national governmental and voluntary health and education agencies. In addition, invitations to send representatives to discuss big city school health problems have been extended to the medical societies, health departments, and education departments serving the two largest cities in each of the nine census regions. Eighty-six consultants drawn from the professions of medicine, education, and public health accepted invitations to serve as discussion leaders for the 12 discussion groups planned. The discussions will center on the relationship of physicians to school health services. The group subjects will be (1) school health service problems in large cities; (2) school health service problems in rural areas; (3) the physician as a consultant in school health education; (4) mental health in the classroom; (5) health aspects of school and community athletic programs; (6) advisory health councils and the school; (7) interchange of health appraisal data on children; (8) medical society school health committees; (9) coordinating health records and examinations; (10) organization and conduct of state and local conferences on physicians and schools; (11) health problems in school transportation; and (12) health of school personnel. The report of the conference will be edited from the notes and reports of the reporters of each discussion group and will be published as soon after the conference as possible. Many state and local conferences were held following the Third National Conference. The Fourth National Conference should give further encouragement to state and local groups to carry on the same thinking at home, and to increase state and local interest in solving school health problems by interprofessional and interagency cooperation.

The consultants have continued to provide assistance to the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, as technical assistants to the several subcommittees. The Educational Consultant, Dr. Hein, is a member of the Joint Committee and is now serving as its Secretary for the third year.

The Medical Consultant, Dr. Dukelow, has served in a consultive capacity to the Council on Medical Service's Committee on Maternal and Child Care. This arrangement has made possible close liaison between the child health activities of the Council and those of the Bureau of Health Education in relation to school health programs. He also has served as a Health Education Consultant to the Joint Committee on Medical Care for Industrial Workers of the Council on Medical Service and the Council on Industrial Health, which has been concerned with the health service for soft coal miners in the eastern bituminous coal area by the United Mine Workers of America.

Health education films, particularly those used for visual education in the schools, are an important educational medium. The consultants review all such films coming to the Committee on Medical Motion Pictures to determine their technical accuracy and applicability.

An informal study of medical school teaching in preventive medicine, public health, and the evolution of physician attitudes toward school health services is being continued from last year. It involves interviews with professors of preventive medicine or other appropriate faculty members of medical schools in cities visited by the medical consultant on other business. To date interviews have been completed at 23 medical schools. Because of the nature of this long-term project it will require a number of years to complete.

Considerable consultant time is given to the conferences and institutes conducted by universities, teachers' colleges, state departments of health and education, and other agencies to improve the understanding of school health services and school health education.

The educational consultant participated in seven national conferences, and the medical consultant has participated in eight. The consultants have also participated in the orientation of foreign visitors and graduate students to the Bureau, particularly in reference to school health policies. During the past year, individuals or groups from many countries and students from many universities have been welcomed to the Division offices.

As a means of promoting interprofessional and interagency relations between the American Medical Association and the educational and health agencies concerned with school health, community organization, and health promotion, both consultants are active in the work of many associations. Within these agencies and in other agencies in which the Consultants do not hold membership, they promote school and child health interests by accepting invitations to address or confer with those attending meetings called by such agencies. Service of this nature has been given to such groups as state and local medical associations and their auxiliaries, various councils, bureaus and committees of the American Medical Association, various national and state health agencies, public health and education departments, parent-teacher associations, professional education associations, and other similar groups. As a matter of policy the medical associations of the state and county in which a meeting is held are always given advance notice that a consultant from the Bureau of Health Education has been invited to and will attend the specified meeting.

The pamphlets that have been the basis of the school health consultation service continue in their usefulness and popularity. These are used extensively in teacher education, community planning, and planning health administration in the school. The two exhibits on school health prepared in previous years are still in demand and are available for showing at annual meetings and conferences of interested organizations.

BUREAU PUBLICATIONS

During the past year the Bureau received 399 communications from a variety of sources requesting information about literature, price quotations on reprints of *Today's Health* articles, sample copies of pamphlets, and materials suitable for display racks, exhibits, county fairs, etc. Orders for pamphlets in quantities, totaling 223,980, were filled. The Order Department sold 368,893 Bureau pamphlets out of stock, making a combined total of 592,873.

Approximately 1,000 copies of a specially prepared Bureau pamphlet, "First Aid Manual," were given away to as many people as a result of advertisements placed in two issues of *Nursing Outlook* and one of *Today's Health.* Exhibits of Bureau literature were prepared for the American Medical Association Public Relations Institute, the National Safety Congress, the Industrial Health Conference, and the New York Annual Meeting.

Fifty-three reprint permissions were sold to 12 publications in the past year, and 115 complimentary reprint permissions were granted.

MEETINGS AND CONFERENCES

The Bureau staff travelled 136,280 miles to attend meetings or address audiences in 29 states and the District of Columbia. They participated in 228 conferences and committee meetings. For various reasons it was necessary to decline 74 engagements.

COOPERATIVE RELATIONSHIPS

National Conference for Cooperation in Health Education.—Membership in this conference was withdrawn in March, 1953, on the grounds that in the past five years it has made no significant accomplishments and has failed in securing financial support from various foundations for a number of proposed projects; also, the American Medical Association support of $50 a year, though nominal, has been out of proportion to the support given the conference by other agencies presumably with equal or perhaps superior financial resources. Under these conditions it was felt that the energies of the Bureau could be expended more profitably in other directions. Member agencies in the conference have been assured that the Bureau is as ready as ever to cooperate with them in appropriate situations.

American Public Health Association, Public Health Education Section, Television Committee.—The Director of the Bureau was reappointed to serve as chairman of this committee for another year. A meeting was held on Oct. 16, 1952, in Cleveland, at which time there was a showing and discussion of selected kinescopes of televised health programs. The suggestions arising out of the discussion of the committee will form the basis for a final report.

Joint Committee on Health Problems in Education of the American Medical Association and National Education Association.—The committee, which was established in 1911 at the suggestion of the American Medical Association, this year completed its 42nd year of activity. Now composed of five representatives of each of the parent organizations appointed by their respective governing bodies, its chief function is to consider principles and policies and to make recommendations on problems affecting the health of children and youth of school age. Membership of the committee during the past year consisted of the following representatives of the American Medical Association: Ray O. Bjork, Helena, Mont.; Fred V. Hein, Chicago, Secretary; Herman M. Jahr, Omaha; Charles Outland, Richmond, Va.; and Carl N. Neupert, Madison, Wis., Chairman. Representatives of the National Education Association were Marjorie Eastabrooks, Olympia, Wash.; Ruth Grout, Minneapolis; John L. Miller, Great Neck, N. Y., Vice Chairman; James Ramsey, Fort Smith, Ark.; and Herbert Walker, New York.

Among the problems considered were methods of keeping current the more than 20 publications that the committee distributes. Two new pamphlets published last year, "Health Conditions Affecting the Personality of School Youth" and "The Physical Educator Asks About Health," have had an unusually wide first year distribution and seem to be filling a definite need. Continuing action toward publication of the Committee's new book, "School Health Services," has proceeded on schedule. It is to be a companion volume to the authoritative text "Health Education," first produced by the committee in 1924 and revised several times since.

During 1953 a number of subcommittees were active in a variety of projects having to do with school health problems. It is anticipated that the subcommittees on "The Nurse in the School" and "The Relation of the School Plant to Health" will complete materials this year that will be published in pamphlet form. Other problems among those listed were handled by statements urging the use of authoritative publications on the subject already available from reliable sources.

The joint committee recommends that (1) physicians, educators, and others concerned with school health be urged to submit pertinent problems to the committee for consideration and appropriate action; (2) extensive distribution and use of the recommendations and publications of the committee be made to guide the development of school health programs along sound lines; and (3) education and medical groups be encouraged to establish cooperative relationships at state and local levels to provide for joint action in improving school health programs.

National Committee for Traffic Safety, President's Highway Safety Conference.—A meeting of the President's Highway Safety Conference was held in Chicago on Oct. 17 and 18, 1952, and was attended by the Associate Director, as alternate for the Director who had previous commitments. Resolutions were presented urging that efforts be directed at stimulating more active development of traffic safety programs at local levels.

National Citizens Committee for Educational Television, Advisory Committee.—The American Medical Association was invited in July, 1953, to join with 28 other national groups as a member of this advisory committee and the Director was appointed to represent the Association and to work with the committee in urging Members to support their local educational stations. The National Citizens Committee for Educational Television Advisory Committee was formed in December, 1952, with help from the Ford Foundation's Fund for Adult Education and the American Council on Education to help local groups establish their own television stations and to protect their interests once they are on the air.

National Committee on Boys and Girls Club Work (4-H) Clubs.—The work of this committee proceeded as usual, with the annual meeting held in Chicago on Dec. 3, 1952, which was attended by Dr. F. V. Hein in place of the Director. This meeting was routine. It was reported that the membership in 4-H has increased since 1921 from 274,000 to 2,000,000 at the present time. During the same length of time, the number of agents to operate the program has increased from 5,300 to 12,600. Some states have fine records in holding youths within the organization for 5 to 10 years. Reenrolment from one year to the next ranges from 42% to 82% in the various states. The future of 4-H looks bright because of fine attitudes on the part of Extension Services toward the organization, greater interest among parents, and the possibility of federal legislation to further assist 4-H Club organization.

Other Assignments.—The Director continues to serve as the official representative of the American Medical Association on the following committees:

American National Red Cross, Advisory Board on Health Services
Cleveland Health Museum, National Advisory Council
AMA-NEA, Joint Committee on Health Problems in Education, Subcommittee on School Health Services Publication
A. M. A. Committee on Television
Safety Organization Subcommittee on Organized Public Suuport of the President's Highway Safety Conference
American Diabetes Association, Committee on Purposes & Policies
National Congress of Parents & Teachers, Advisory Committee on Health & Summer Round-Up.
National Society for Medical Research, Executive Committee and Board of Directors.

United States Government Agencies.—The Bureau continues to cooperate by correspondence or otherwise with many government agencies.

MISCELLANEOUS

The Bureau entertained and arranged observation schedules for 20 visitors, including one or more from each of the following countries: Brazil, Egypt, England, Finland, Germany, India, Iran, Japan, Nepal, Tunis, and Yugoslavia. In most instances arrangements were made for these visitors to tour the American Medical Association building, study the particular departments that interested them most, and become acquainted with the work of other Chicago agencies, such as the American Dental Association, the American College of Surgeons, the American Hospital Association, medical schools and universities, health departments, social agencies, public schools, and museums.

THE ST. LOUIS MEETING

In this and the succeeding issue of THE JOURNAL will appear reports of the officers of the American Medical Association, the scientific program, and descriptions of the technical exhibits for the St. Louis meeting of the Association. Several years ago a midyear meeting of the Association was held in St. Louis, and those in attendance will remember the virtues of this community as a convention city.

The Clinical Meeting (this is the seventh) features programs for the general practitioner. It also is the time when the yearly reports of the work of the various A. M. A. offices are presented to the House of Delegates. Unlike the annual meeting, the scientific program is not divided into sections, although it features topics in broad fields. Thus the registrant can hear papers, attend conferences, and see demonstrations on subjects ranging from opportunities for research in general practice to pain, cardiovascular diseases, virus infections, pulmonary diseases, cancer, neurological and psychiatric problems, surgery, arthritis, dermatitis, jaundice, cyanosis, toxemia of pregnancy, leukemia, and other topics too numerous to mention.

As at all meetings of the Association, scientific exhibits will play an important part in the proceedings. Also of interest will be the motion pictures and the color television program. The latter has become so popular and effective that it offers promise of opening a new door to postgraduate education. On Thursday evening, December 3, the NBC Television Network will carry a program of convention activities. Local newspapers across the nation will contain information on the time and channels.

Hotel reservations for the St. Louis meeting should be made by application to "Chairman, American Medical Association Subcommittee on Hotels, Hotel Reservation Bureau, Room 406, 911 Locust Street, St. Louis 1, Mo." Applications should not be sent to A. M. A. Headquarters in Chicago. Applicants should indicate preference of hotel (first, second, third, and fourth choices), type of room or suite desired (including price), and time of arrival and departure. This meeting offers appeal to specialists as well as to the general practitioner, and it is not too early now to make hotel reservations.

INFLUENZA

The World Health Organization has issued a symposium[1] on influenza that contains a vast amount of information. Much of this is highly technical and will be of interest chiefly to research workers, but much also will be of interest to physicians in practice. The erratic behavior of influenza, which has puzzled epidemiologists for many years, is attributed to the variability, unequaled by most disease agents, of the influenza virus. It has been shown that although the disease may be produced by either of the two commoner and antigenically separate viruses, A and B, and not uncommonly by both at once, major outbreaks can be ascribed chiefly to virus A. A wide variety of strains of this organism have been studied, and it is believed that a succession of antigenic changes is occurring, because over the years one prevalent strain will disappear to be replaced by another that is later supplanted by a third. Whether the capacity of virus A for variation is unlimited has not yet been determined.

In order to achieve worldwide coordination of all aspects of this disease WHO now sponsors the World Influenza Center, with headquarters in London and a network of associated laboratories in 42 countries. In recent years the identification of the virus by hemagglutination-inhibition tests has been used in preference to complement-fixation or cross-protection tests in mice because it is the cheapest and technically the simplest. It is difficult to find the influenza virus in any locality in the intervals between epidemics. It has been postulated that the reservoir of infection may be in chronic pulmonary lesions in man in a form unrecognizable by the usual tests. Belief in the hidden existence of the virus is based on the following factors: (1) inability to find active virus over long periods; (2) minor epidemics in early summer preceding widespread outbreaks in the fall; (3) outbreaks occurring almost simultaneously in widely separated centers; and (4) the appearance of influenza simultaneously over large areas, the spread being too rapid to be explained by case to case transmission. It is concluded in the WHO symposium that in the spread of epidemics two factors are involved: (1) the existence of a "basic virus" as yet undetectable until activated and responsible for multicentric outbreaks and (2) the element of spread, which under favorable conditions carries the infection to susceptible groups and results in extensive epidemics.

In a study of serum antibody levels in various age groups it was found that children's serums showed a high level for FM1 and FW-1-50 strains of influenza virus A and essentially no antibody for the WS or PR8 strains. Adult serums on the other hand revealed a high antibody content for PR8 and moderate titers for WS and A′ strains. The antibody levels against PR8 increased in 1944 after the epidemic and remained high for about eight years. Although the measurement of antibody levels may aid in estimating the susceptibility of a given population to a given virus, the relationship between antibody titer and immunity is unfortunately not always consistent, because the disease sometimes occurs in persons with high antibody levels and others with low levels may escape infection. Factors other than the amount of antibody circulating in the blood must, therefore, influence immunity to this disease.

---

[1] Influenza, Bull. World Health Organ. (No. 5-6) 8:591-823, 1953.

Exact information on the morbidity and mortality from influenza is difficult to obtain. Although where the disease is reportable the reporting is both incomplete and irregular, especially from rural areas, there is evidence that deaths from influenza in a unit population have been decreasing in all countries for which data are available. The exact meaning of this is not clear. The elimination of false reporting by positive virus identification, the use of modern therapy, and changes in the rules governing the selection of the underlying cause of death when more than one cause is given may all be factors in this decrease.

Through the use of high speed centrifugation and the electron microscope knowledge of the morphology of the influenza virus has been greatly increased. The virus can be shown to consist of an elementary body and a soluble substance. The properties of these two components are very different. The soluble substance consists of small, noninfective, but highly antigenic particles that are not easily seen even with the electron microscope. It can be demonstrated only by complement-fixation tests. Antibodies to this substance develop after infection but not after vaccination. Virus infectivity is found in the larger elementary bodies. These bodies also cause hemagglutination and are capable of stimulating the production of complement-fixing antibodies that are different from those associated with the soluble substance. Studies of the enzymatic virus-host cell interactions give promise of a better understanding of the kinetics of intracellular growth and may eventually lead to a means of chemotherapeutic control of the disease.

Study of the influenza virus in the allantoic cavity of the chick embryo is initiated by adsorption of a virus particle to mucoprotein receptors on the cell surface. This is followed by a period of a few hours in which no viable virus can be extracted from the infected cells. At some stage before the virus is liberated into the allantoic fluid, soluble complement-fixing antigen, hemagglutinin, and viable virus in that order can be extracted from disintegrated infected cells. The average infected cell may liberate about 90 virus particles within two or three hours. Most infected cells show no sign of morphological damage when the first virus particles are liberated. The earliest sign of change is an increase in ribonucleic acid in the cytoplasm. This may or may not be followed by structural damage. Subsequent waves of infection are chiefly by way of the virus liberated into the allantoic fluid. The soluble complement-fixing antigen is a particulate agent much smaller than the virus and has a species-specific antigenic pattern. Its major component is nucleoprotein containing ribonucleic acid, and except for its specific antigen it cannot be distinguished from the microsomal fraction of normal cells.

Some of the early difficulties in preparing a potent A and B vaccine have been overcome by methods of concentration of the virus using the adsorption of the virus onto the erythrocytes of the chick embryo. The virus is inactivated by formaldehyde, and a mild bacteriostatic is added. Protection begins about seven days after vaccination and lasts several months. Although it is not effective for all strains of the virus, it has been demonstrated that some protection can be obtained by the use of vaccine strains that are not identical to those prevalent in an epidemic. There appears to be a more rapid decline in antibody titer after the initial postvaccination rise in young children than in older groups. Investigations have shown that the use of virus first emulsified in mannitol mono-oleate and then suspended in a light mineral oil gives a vaccine that is free from the side-reactions attending the use of other adjuvants and that will produce greatly increased and longer lasting antibody titers as compared with aqueous vaccines. The cost of production of the modified vaccine is also much less than that of aqueous vaccine. It would seem clear, then, that vaccination for influenza is effective when the vaccine used is properly prepared and has not lost its potency. Further improvement in the production of influenza vaccine will undoubtedly be made in the near future.

PERITONEOSCOPIC CHOLANGIOGRAPHY

The diagnosis of hepatic and biliary disorders is difficult despite various liver function tests, including needle biopsy of the liver and cholecystography.[1] Unfortunately, oral cholecystography is most reliable when the biliary system is normal and least reliable when disease is present.[2] Although cholangiography is almost routinely used during and after exploratory laparotomy when biliary tract disease is suspected, the technique of peritoneoscopic cholangiography described by Lee,[3] which has definite advantages, seems to have been neglected. Keil and Landis[4] found it to be a relatively harmless procedure and recommended its use when a differentiation between primary hepatocellular damage and damage due to common duct stone could not be made by other methods. Such diagnostic problems are relatively common, and differentiation is important because patients with far-advanced hepatic disease do not tolerate laparotomy well. Peritoneoscopic cholangiography permits visualization of the gallbladder, cystic duct, and common duct in their entirety and is an especially valuable procedure when oral and intravenous cholecystography fail. Mild reactions resulting from injecting the contrast medium into the peritoneal cavity or the wall of the gallbladder reported earlier can be prevented by the simple expedient of assuring a free flow of bile through the needle before iodopyracet is injected.[2] This diagnostic measure will spare many patients a needless operation, and those who have a stone in the common duct "may be spared the delay which leads to severe hepatic damage and suppurative cholangitis."[4] For this reason it should be used in peritoneoscopic examinations in which there is any question of intrahepatic or extrahepatic obstruction.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

There are homes in this country where the onset of chronic illness in any member of the family would create an economic burden. The development of an adequate program of medical care for those afflicted with long-term ailments is one of the major problems in the health field service. The American Medical Association has long recognized the importance of this problem and has actively supported various movements designed to find a solution.

In 1949, the A. M. A. helped to found the Commission on Chronic Illness, for the express purpose of making a detailed study of the whole problem. Since that date the Association has contributed financially and in many other ways to the support of the commission. The Association has also been active in support of the vast research programs of our national voluntary health organizations, such as the American Cancer Society, American Heart Association, and the National Tuberculosis Association. Aside from sponsoring research programs, their efforts are devoted largely to education in the prevention and treatment of chronic diseases. I know that the Board of Trustees has followed the developing program of the Commission on Chronic Illness with keen interest. The commission has provided a useful vehicle for study of this major problem and a medium through which we can readily combine our efforts with other national organizations that have a big stake in working out an adequate medical care program for the victims of prolonged illness.

Most physicians today are seriously concerned over the great financial strain that a long-term illness imposes on a family. Too often doctors see the skills of registered nurses used where a practical nurse or a housekeeper could serve the purpose as well. Those of us who serve on hospital planning or operating boards know that our general hospitals are not designed for the care of many patients with chronic illnesses, but where else can we put them? If we are to build other facilities, where are we to build? These are only a few of the problems that practicing physicians are facing every day. And statistics show that the problem is growing as our knowledge of averting and controlling the acute diseases increases.

To tackle the questions, the A. M. A. Board of Trustees voted to join with the American Hospital Association, the American Public Health Association, the American Public Welfare Association, and the U. S. Public Health Service in sponsoring a National Conference on Care of the Long-Term Patient. This conference will be held in Chicago March 18-20, 1954. Financing for preconference activities and the conference itself is in the form of grants totaling $35,000 by the Rockefeller Foundation, the Liberty Mutual Insurance Company, the New York Life Insurance Company, the Metropolitan Life Insurance Company, and the Equitable Life Assurance Society. This meeting is developing as a logical sequence to the previous National Conference on the Preventive Aspects of Chronic Illness, which was held in Chicago in March, 1951. The conference will be focused on the health services that are needed by the approximately 4 million Americans who have been substantially disabled as a result of long-term illness or other impairments. The problem now is not how to arouse interest in the action that must be taken but rather how best to provide the care that is needed.

There has been much experimentation in various parts of the country with different facets of the problem, and a number of organizations and individuals have been successful to a limited extent. The commission took advantage of this practical local experience in making preparations for the conference and assigned various segments of the subject to small study groups that dealt intensively with their respective assignments. The material produced by these study groups will provide the basis for discussion at the conference. The study groups started meeting in May of this year, and their reports are scheduled to be completed in November. The subject matter for the conference itself has been divided into five major categories concerning the chronically ill—the patient at home, the patient in an institution, integration of facilities, research needed, and methods of financing.

As President of the American Medical Association I wish to commend the work done so far by the Commission on Chronic Illness. I also feel that a vote of thanks is due the members of the various study groups who have worked so diligently at their assignments in the past few months. Their combined effort toward solving this urgent problem is certainly worthy of strongest support by the physicians of the United States.

Edward J. McCormick, M.D.,
Toledo, Ohio

ORGANIZATION SECTION

CANCER RESEARCH THEME OF SECOND TELECAST

Tremendous efforts and studies being undertaken in the fight against cancer will be highlighted during the second of the fall television series of "The March of Medicine" at 10 p. m. (E.S.T.), Nov. 5. Television audiences will find local time and channels in newspaper advertisements in cities carrying the program. The telecasts, to be carried over 69 National Broadcasting Company stations in the United States and three Canadian stations, are produced by Smith, Kline and French Laboratories in cooperation with the American Medical Association.

Presented as a public service to create a greater awareness of the extensive research being carried out by the medical profession, the telecasts are live presentations from some of the nation's leading medical centers. The third in the series, to be presented Dec. 3, will point up medical progress as reported at the seventh annual A. M. A. Clinical Meeting at St. Louis.

Among the physicians appearing on the Nov. 5 program will be James W. J. Carpender, M.D., associate professor of radiology and director of radiation therapy at the University of Chicago Clinics and Argonne Cancer Research Hospital; Charles B. Huggins, M.D., director of the Ben May Laboratory for Cancer Research, University of Chicago; David A. Karnofsky, M.D., associate attending physician, chemotherapy service, Memorial Hospital, New York; Alton Ochsner, M.D., William Henderson Professor of Surgery at Tulane University of Louisiana School of Medicine; Wendall M. Stanley, Ph.D., Nobel laureate, director of the virus laboratory at the University of California, Berkeley; Harold C. Urey, Ph.D., atomic scientist and Nobel laureate, Ryerson Professor of Chemistry at the Institute for Nuclear Studies at the University of Chicago, and Edward L. Tatum, M.D., professor of biology, Stanford University.

ARTICLE IN COLLIER'S MAGAZINE

In the Oct. 30 issue of *Collier's* magazine appeared an article titled "Why Some Doctors Should Be in Jail" by Howard Whitman. Included in the article was a statement by Dr. George F. Lull, Secretary and General Manager, of official A. M. A. policy with respect to fee splitting, and comments by other medical leaders. After the publication of this article many physicians complained about the title and much of the content. In preparing the article the author requested a statement from the A. M. A. regarding its policy with respect to fee splitting, and the statement that appears in the article by Dr. Lull was provided in response to that request. The contents of the article and the title were prepared by the author and the magazine respectively and were at no time subject to review or revision by the Association, which was regrettable.

PUBLIC RELATIONS CONFERENCE IN ST. LOUIS

Medicine's principal PR problems for 1954 will be outlined by the keynote speaker, Dr. Walter B. Martin, A. M. A. President-Elect, at the American Medical Association's sixth annual Medical Public Relations Conference. Geared primarily for physicians, this year's conference is built around the theme "Facing up to PR Facts." The one day meeting will be held Monday, Nov. 30, in the Gold Room of the Jefferson Hotel in St. Louis, just before the A. M. A.'s Clinical Meeting. The morning program will feature a modified symposium on "Making a PR Program Work" to consider both state and county society PR programs. The luncheon speaker, Dr. John P. Spiegel, a psychiatrist from Chicago, will discuss "What Motivates the Public's Attitude Toward Medicine?" Two topics will be discussed during the afternoon program. One will be devoted to ways of selling our economic system and the other will be on mending our PR fences by policing causes of unfavorable publicity. Especially invited are medical society public relations chairmen, society officers, A. M. A. delegates, and staff employees of state and county societies. Registration opens at 9 a. m., and the conference will start at 10 a. m.

DISBURSEMENT BY NATIONAL FUND TO MEDICAL SCHOOLS

Now is the time for maximum effort on the part of every state and county society committee to insure a record income for 1953 for the American Medical Education Foundation. If every effort is exerted in this direction, the last day of December will see the foundation's income standing in excess of one million dollars for the first time since its inception. During the second and third week of November, more than 150,000 subscribers to The Journal in the United States will receive literature and a letter explaining the value of reviewing their probable income tax to see if a contribution to the foundation might serve the dual purpose of lessening their income tax and at the same time helping the nation's medical schools. By their personal efforts, added to this mail campaign, physicians can increase the amount of money raised in their state or county and elevate the relative position of their state in the record.

The number of contributors has increased more than 100% during the current year, and, on Oct. 1, the income was in excess of $907,000 or slightly more than was raised during all of 1952. Every dollar that the state and local committees turn in from now until Dec. 31 will expand the total funds raised and push the total ever closer toward the million dollar mark. The foundation has received $924,741.63 from 14,366 contributors at this writing. Let's all go to work at once and watch this total grow. Hiram W. Jones, executive secretary of the foundation, has just released a list of disbursements made by the National Fund for Medical Education last July to our medical schools.

RURAL HEALTH CONFERENCE TO BE HELD IN DALLAS

"Let's Put More 'U' in Comm*Unity* will be the theme of the ninth National Conference on Rural Health, sponsored by the A. M. A. Council on Rural Health, to be held at the Baker Hotel in Dallas, March 4-6, 1954. Leaders in the fields of medicine, agriculture, education, and public health will attend the formal sessions, which begin at 2 p. m. on Thursday, March 4, and continue through Saturday, March 6, ending with a luncheon meeting at 1 p. m. Problems of nutrition and costs of medical care and methods of prepayment will be the principal subjects to be discussed.

Following the practice of the last few years, an informal, preconference session for doctors only will be held at 10 a. m. on Thursday, March 4. Council Chairman F. S. Crockett, Lafayette, Ind., said this session would be devoted to problems confronting physicians who are members of state rural health committees or committees handling rural health problems. Physician participation at the grass roots and problems pertaining to health insurance matters are among the major subjects to be considered.

PHYSICIANS AND SCHOOLS CONFERENCE

More than 200 persons—physicians, public health officials, and educators—attended the recent fourth National Conference on Physicians and Schools, sponsored by the A. M. A. Bureau of Health Education. Thirty-eight states and the District of Columbia were represented. Every group discussion centered around the problems of attaining better health of children of elementary and high school ages. A. M. A. President E. J. McCormick, who was one of the dinner speakers, touched on what he termed a major point in the mortality rate among children, namely, accidents. He said accidents take the heaviest toll—14,000 deaths a year. That, he stated, is where health educators must put the stress because the figure represents more than the next six causes of death combined.

CIVIL DEFENSE

Plans for Special Weapons Defense. Part I: Defense Against Biological Warfare Agents

Following is the first of three articles on medical civil defense plans that have been prepared for the state of Maine. These plans are being published as samples for those states that have not as yet completed this phase of medical civil defense planning.—Ed.

The Committee on Civil Defense of the Maine Medical Association and the civil defense authorities for the state of Maine have completed, after three years of extensive work, State, County and City Organization and Operation Plans for Special Weapons Defense.

These plans, which are divided into three sections (see charts 1 and 2) as follows, Biological Defense, Chemical Defense and Radiological Defense, are designed to:

1. Provide adequate protection at the lowest possible cost and with the least inconvenience to all concerned.

2. Utilize equipment and supplies already available in the State, and conserve the State's manpower to the fullest extent.

The judicious use and the conservation of manpower and of equipment at hand were both considered to be items of such paramount importance in Civil Defense planning that it was deemed advisable to recommend that:

1. Multi-purpose types of Decontamination Units be organized at the county and at the city levels and that they be provided with the basic equipment and necessary supplies, be staffed with a minimum of qualified personnel and that the units be instructed and properly trained in the special techniques to be used when decontaminating for bacteriological, chemical or radiological warfare agents.

2. Dual purpose types of Bacteriological and Chemical Reconnaissance and Detection Units be organized at the county and city levels, that they be provided with the basic equipment and necessary supplies, be staffed with a minimum of qualified personnel and be instructed and properly trained in the special techniques to be used when either bacteriological or chemical warfare agents are suspected.

3. Single-purpose types of Radiological Detection Units be organized only at the state level, be provided with the necessary detection instruments by the State Civil Defense Agency, be sponsored and trained by the Department of Physics at the University of Maine and at each of the four colleges in the state.

A PLAN FOR DEFENSE AGAINST BIOLOGICAL WARFARE AGENTS

The indiscriminate use of biological warfare agents might accompany any enemy attack with either conventional high explosive bombs or with the newer missiles with chemical or atomic warheads; but their most logical use would seem to be by saboteurs at local levels to interfere with mobilization, to attack key personnel in military or civilian positions, to incapacitate large military or industrial establishments or to curtail production through destruction of crops or domestic animals used for food. Bacterial agents of various types or the toxic products of certain pathogens that make people or their live stock ill or destroy their lives; and synthetic hormones that control growth and fruit bearing functions of most plants have been developed which can kill crops and vegetables.

Hence, the Federal and State Civil Defense Authorities are faced with the necessity of preparing defenses capable of coping with all such eventualities. An attack must be recognized promptly, the biological agent identified, the disease diagnosed, and the potential epidemics controlled or neutralized by aggressive public health measures strongly supported and implemented by physicians and health agencies within the area or by rigid plant or animal quarantine in contaminated areas by the Department of Agriculture.

It is implicit, therefore, that the State plan of organization include all scientific agencies dealing with human communicable diseases such as the state and local Departments of Health, physicians, dentists and nurses; and all state and local government agencies having to do with the protection of man's food supply, such as the State Department of Agriculture, the Agriculture Extension Service, the State University School of Agriculture and the experimental stations, the State Fish and Game Commission, the State Forestry Service, etc. There must be the utmost cooperation between hospitals, State Department of Health, State Department of Agriculture and University and College laboratories throughout the State. Finally, the State Biological Defense Section should, at all times, cooperate and coordinate its activities with the Federal and Regional Special Weapons Defense sections.

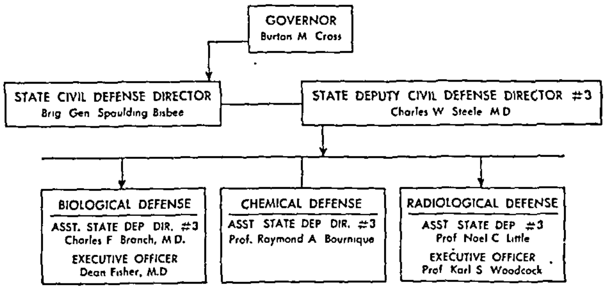

Chart 1.—Special weapons defense organization plan.

Duties and Responsibilities.—The duties and responsibilities assigned by the State Civil Defense Agency to the Assistant State Deputy Director #3 in charge of Biological Defense are as follows:

1. To outline, establish and control the organization, activities and methodology of the Biological Defense Division at all levels within this State.

2. To recruit and train personnel to handle the minute details of the technical aspects of detection, identification and decontamination.

3. Through the State Civil Defense Headquarters Office, to provide means and materials to those laboratories designed as regional diagnostic centers, and to implement their personnel assignments when required, for training or under conditions of attack or of major disaster.

4. To have at all times full knowledge of Biological Warfare offensive possibilities of or by potential enemy powers, or their saboteur agents.

5. To strive for early recognition of any such biological warfare attack by an enemy power or by subversive agents.

6. To conduct the necessary laboratory examinations of water, food, air, plants, animals and other vectors required to detect and identify any specific biological agents used in an attack.

7. To provide the necessary bacteriological data which will be required to assist the State and local Departments of Health, the State Department of Agriculture and other such responsible health agencies to localize and properly isolate all

contaminated areas within the State and to effectively quarantine infected persons, other infected animals and diseased plants as the case may be.

8. To provide the specific laboratory data which will permit practicing physicians, veterinarians and county extension agents to confirm clinical diagnosis, prescribe specific remedies when such are available and to instigate suitable isolation or quarantine measures designed to prevent the further spread of the disease-producing agent.

9. To outline suitable decontamination procedures for personnel, vital buildings and essential terrain in areas involved.

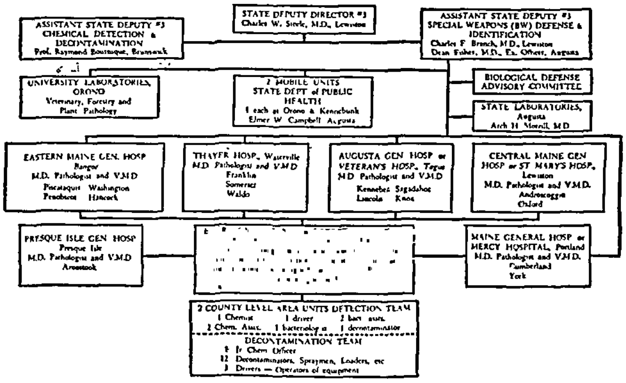
10. On request, to provide for proper Civil Defense authority, such factual and scientific information concerning Biological Warfare Defense as may be required to allay fear of the unknown that might give rise to mass hysteria.

Organization.—The Civil Defense Organizational Plan for Special Weapons follows:

1. Assistant State Deputy (Biological) Director #3. (Responsible to the Health Services and Special Weapons Defense Deputy Director.)

2. State Biological Defense Executive Officer. (The Director of the State Bureau of Health. Responsible to the Assistant State Deputy [Biological] Director #3.)

3. Biological Defense Advisory Committee. This committee will provide the Assistant State Deputy (Biological) Director #3 with the specific information needed in all the above mentioned fields of endeavor here in Maine. This group will operate at the state level and will consist of:



STATE DEPUTY DIRECTOR #3
Charles W. Steele, M.D., Lewiston
ASSISTANT STATE DEPUTY #3
CHEMICAL DETECTION & DECONTAMINATION
Prof. Raymond Bousquet, Brunswick
ASSISTANT STATE DEPUTY #3
SPECIAL WEAPONS (BW) DEFENSE & IDENTIFICATION
Charles F. Branch, M.D., Lewiston
Dean Fisher, M.D., Ex. Officer, Augusta
UNIVERSITY LABORATORIES, ORONO
Veterinary, Forestry and Plant Pathology
2 MOBILE UNITS
STATE DEPT of PUBLIC HEALTH
1 each at Orono & Kennebunk
Elmer W. Campbell Augusta
BIOLOGICAL DEFENSE ADVISORY COMMITTEE
STATE LABORATORIES, Augusta
Arch H. Morrell, M.D
EASTERN MAINE GEN. HOSP
Bangor
M.D. Pathologist and V.M.D
Piscataquis Washington
Penobscot Hancock
THAYER HOSP., Waterville
M.D. Pathologist and V.M.D
Franklin
Somerset
Waldo
AUGUSTA GEN HOSP or
VETERAN'S HOSP., Togus
M.D. Pathologist and V.M.D
Kennebec Sagadahoc
Lincoln Knox
CENTRAL MAINE GEN HOSP or ST MARY'S HOSP., Lewiston
M.D. Pathologist and V.M.D.
Androscoggin
Oxford
PRESQUE ISLE GEN HOSP
Presque Isle
M.D. Pathologist and V.M.D
Aroostook
MAINE GENERAL HOSP or
MERCY HOSPITAL, Portland
M.D. Pathologist and V.M.D.
Cumberland
York
2 COUNTY LEVEL AREA UNITS DETECTION TEAM
1 Chemist 1 driver 2 bact. assts.
2 Chem. Asst. 1 bacteriologist 1 decontaminator
DECONTAMINATION TEAM
1 Jr Chem Officer
12 Decontaminators, Spraymen, Loaders, etc
3 Drivers — Operators of equipment

Chart 2.—Civil defense plan for bacteriological defense.

a. Three physicians especially qualified in the various fields of human microbiology and parasitology, one of whom is a representative of the State Bureau of Health.

b. Three representatives from the State Department of Agriculture to include a plant pathologist, a veterinarian and a tree pathologist or entomologist.

c. A representative from the Department of Inland Fisheries.

d. A representative from the Department of Sea and Shore Fisheries.

This advisory group or technical panel will assist the Assistant State Deputy Director #3 (Biological) in the development of a program of laboratory techniques for the detection and identification of biological warfare agents and will assist in working out the most effective methods for combating such agents and decontaminating infected areas. They will assist in arranging for and implementing the organization and training of regional microbiological detection teams to operate under the direction of the chiefs of the Divisional Laboratories in various sections of the State.

4. State Bureau of Health Pathologist. To direct the State Bureau of Health's central diagnostic pathological and bacteriological laboratory at Augusta.

5. Senior Biological Defense Officer, Regional. (To be a physician or University or College Bacteriologist or Pathologist, especially trained in microbiology and parasitology, who now is or who may act as the Chief of the "District Diagnostic Laboratory," as prescribed in the next paragraph.)

6. District Diagnostic Laboratories will be established in six localities throughout the State.

a. These District Laboratories will provide biological defense service for the counties enumerated as follows:

	City	Name of Institution	Counties to be Served
1.	Presque Isle	Presque Isle Gen. Hosp.	Aroostook
2.	Bangor	Eastern Maine Gen. Hosp.	Hancock, Penobscot, Washington, Piscataquis
3.	Waterville	Thayer Hospital	Franklin, Somerset, Waldo
4.	Togus	Veterans Administration	Kennebec, Lincoln, Sagadahoc, Knox
5.	Lewiston	Central Maine Gen. Hosp.	Androscoggin, Oxford
6.	Portland	Maine General Hospital	Cumberland, York
7.	Orono	State University-Forestry Plant and Veterinary Laboratories	All counties in State

b. Two Biological Identification Units will be organized at each District Diagnostic Laboratory and will be directed and trained under the Regional Senior Special Weapons Officer. These teams shall be essentially mobile in type so that they can function alone under what conceivably may be the most primitive laboratory conditions or they may be attached to any of the State Mobile Reserve Battalions. Each "Biological Identification Unit" will be composed of: 1. One Chief Bacteriologist, 2. Three Trained Technicians (especially trained volunteers who may or may not be regular medical technologists).

7. Senior Chemical and Bacteriological Officer, State Department of Health Mobile Laboratory Units

The senior employee in each of the State's Department of Health Mobile Laboratories will function as the Senior Chemical and Bacteriological Officer for his mobile unit in time of an emergency certified by the Governor; and he will be responsible to the "State Biological Defense Executive Officer" who is the Director of the State Bureau of Health.

8. Two State Department of Health Mobile Laboratory Units

It is planned to set up within the existing State Department of Public Health Mobile Laboratory Units, supplementary detection and diagnostic equipment that may be used in case of bacteriological or chemical attacks. These two units would then serve as mobile laboratories for detection and identification of chemical and bacteriological warfare agents. The State Advisory Panel will have the assignment, planning and implementing of these existing units and in the organization, equipping and training of any additional mobile units that may be required in the future.

9. Senior Biological Officer, County

This officer, on the staff of the #3 Deputy County Civil Defense Director, will be responsible for developing and promoting within a county, the State Biological Defense program or any other such program as may be approved by the State Deputy Civil Defense Director #3 and his Special Weapons Assistants.

This Civil Defense Plan for Bacteriological Defense is shown in outline form in chart 2.

Methods.—A. Decontamination Procedures for:

1. Buildings, Floors, Walks, Roads, Streets, Equipment, etc.

a. Liberal sprinkling of lime or chloride of lime may be used to decontaminate grounds, walks, concrete floors, and to make protective small work areas where needed.

b. Large impervious surfaces such as stone or brick walls of buildings, hard surface drives, walks, limited street areas, tile or concrete floors, etc., may be decontaminated by application of detergents followed by water streams.

c. Steam generators equipped with steam hoses may be used to decontaminate large impervious surfaces of the type enumerated under "b" above.

d. Portable flame or acetylene burners when available might be used to decontaminate certain types of metal equipment or other types of non-inflammable structures.

e. Exposure to sunshine or to ultra-violet light will satisfactorily sterilize all but the spore-bearing bacteria and certain stable toxins such as those produced by the Botulism organisms.

f. Exposure to drying and heat will kill certain bacteria and virus agents.

g. Exposure to moisture and cold will destroy other virus infections and certain toxins.

2. Personnel Assigned to Detection and to Decontamination Units

a. Non-pervious clothing, rubber gloves, rubber boots, should be worn by the personnel of detection and of decontamination units while on duty in areas contaminated or suspected of being contaminated by BW agents. Impregnated clothing of the type used by chemical warfare personnel is said to afford protection against most BW agents.

b. The non-pervious clothing, rubber gloves and rubber boots should be removed and placed in suitable containers for sterilization or for destruction when the workers leave the contaminated area.

c. All personnel should then pass under a series of showers where suitable detergents are used along with vigorous scrubbing of skin.

d. A complete change of clean clothing must be provided for workers after they leave the showers.

e. The canister mask should be worn and should protect detection and decontamination personnel against inhalation of BW agents suspended in aerosol mixtures both during and immediately after an enemy BW raid.

f. The number of personnel assigned to decontamination work should obviously be kept as limited as possible.

3. Disaster Victims Caught in the Open and Contaminated by Enemy BW Agents Dispersed in Aerosol Form:

a. Self-Help Procedures

1. Don individual non-canister type gas mask if one is carried by the victim at time of raid.

2. Cover nose and mouth with double thickness cloth made from handkerchief, scarf or other article of clothing if mask is not available in an effort to prevent inhaling the BW agents suspended in the aerosol.

3. Seek cover inside a building or in protection of a doorway or other shielding object whenever feasible.

4. Keep doors and windows to buildings tightly closed during and for some time immediately following a known BW raid.

5. Do not eat food or drink water or other liquids that might have been exposed to BW agents during the enemy attack.

b. First Aid Procedures

1. Remove all clothing from disaster victims who are suspected of having been exposed to BW agents before they are admitted to any collecting station or to any hospital installation and place contaminated clothing in containers provided for that purpose.

2. All such ambulatory personnel should then pass under a series of showers where suitable detergents are available for use along with vigorous scrubbing of the entire outer surface of the body. See Charts III and IV.

3. All such non-ambulatory disaster victims will have to have clothing removed and placed in suitable containers and will require bathing by Medical and Hospital personnel before they can be admitted to the main wards and rooms in the hospital proper.

4. Clean hospital clothing must be provided for the disaster victims as they leave the showers in the decontamination truck.

B. Equipment for use by Veterinarian Decontamination Crew

6 manure forks (five-tine)
3 scrapers (long-handled)
3 ship scrapers
3 flat shovels (long-handled)
2 scoop shovels
3 hoes
3 garden rakes
3 heavy brooms
1 fiber push broom
1 ax
1 crowbar
1 pick
1 hatchet
1 pair pliers
2 milk cans (10 gallon)
1 pail (galvanized, 12-quart)
1 force pump
100 feet ¾-inch pressure hose
1 spray gun
4 rubber coats
6 pair rubber gloves
24 suits (overalls and jumpers)

C. Specific Identification Tests for BW Agents to Be Performed by the State Department of Health Laboratory and by the Specified General Hospitals that are to Provide Personnel and Equipment for Regional BW Laboratories.

1. The orthodox standard bacteriological culture and identification methods will by necessity be used for the present by the laboratory personnel when testing for suspected BW agents.

2. Rapid and specific identification tests for all major BW agents are being developed by the U. S. Public Health Services and by the Biological Warfare Section of the Armed Forces and these methods and procedures will be made available to the Maine State and Regional BW laboratories just as soon as this information is released by FCDA.

D. Collection of Specimens and Materials to Be Sent to Biological Warfare Diagnostic Laboratories.

1. General Information and Directions:

The following brief outline for collecting and processing materials suspected of being contaminated with Biological Warfare Agents is included for the benefit and guidance of those volunteers who are not regular medical technologists. Those procedures common to the collection and processing of all types of materials and specimens to be forwarded to designated Biological Diagnostic Laboratories are as follows:

a. Information Card—must be filled out and accompany every specimen and should include:

1′ Nature of BW specimen collected.

2′ Type of Biological Warfare agent suspected.

3′ Where and when specimen collected.

4′ Name of diagnostic team or person collecting specimen.

5′ Name of person to whom report is to be sent.

6′ Address of laboratory to which specimen is to go.

b. Biological Warfare Specimens and Materials for Study—should always be dispatched to the nearest Regional or State Diagnostic Laboratory by the quickest available means of transportation.

c. Standard Type Containers—should be used for the collection of certain materials such as water, air, food, human excreta, etc., and should be used whenever available by detection units.

d. Clean Half-Pint, Pint, Quart or Half-Gallon Canning Jars—of suitable size can be substituted when standard shipping containers for water, milk, food, insect or animal specimens are not readily available.

1′ *A jar rubber must be used under the cover on every canning jar* when it is closed to prevent leaking of fluid contents while in transit.

2′ All bottles and corks or caps must be clean and if facilities are available, these items are preferably boiled prior to use.

3′ The inside of the cover and the inside of the jar should not be touched while the bottle is being filled and recapped.

4′ Great care must be exercised when filling the jar to make sure that none of the material suspected of being contaminated with a BW agent gets on the outside of the container where it could infect or harm persons transporting the specimen to the laboratory.

5′ An Identification Card must be completed and attached to the outside of every jar used for a specimen container.

e. A small wide-mouth jar or bottle may be substituted when a standard specimen bottle is not available for human excreta, or small insect or animal specimens.

1′ Cork stoppered bottles with wide mouths are preferable.

2′ Screw cap wide-mouth bottles must have a suitable liner in the cap to prevent leaking of liquid specimens and the cap should be secured with adhesive tape.

3′ All bottles and corks or caps must be clean and, if facilities are available, these items are preferably boiled prior to use.

4′ The same precautions apply here in regard to the prevention of contamination to the inside and outside of the bottles when filling as was outlined under d-3′ and 4′ above.

5′ An identification tag must be completed and attached to each specimen bottle prior to its dispatch to the laboratory.

2. Specific Instructions for the Collection of Various Types of Materials Contaminated by Biological Warfare Agents.

Chart 3.—Method for adapting vehicles for use as decontaminators for personnel.

a. Collection of Water Specimens (Raw and Treated)

1′ Water Specimens to be collected from intact municipal system faucets:

a′ Allow water to run freely from tap for a few minutes.

b′ Remove stopper from standard container or cover from one-half gallon jar, place container under the faucet without touching mouth of bottle, fill container almost to top with water, replace stopper and secure it by replacing cloth cover on standard container or by securing the jar cover over a jar rubber in the usual manner.

2′ Water Specimen to be collected from streams, ponds or reservoirs.

a′ Wash the hands thoroughly with soap and water to free them from bacteria before taking the water sample.

b′ Remove cloth and stopper from shipping container or cover from clean glass jar.

c′ Reach out as far as possible against the current, submerge the bottle about one foot beneath the surface with the mouth of the bottle or jar upstream and allow to fill.

d′ Replace and secure stopper or jar cover as described above.

3′ Water Specimen to be collected from well or spring.

a′ Pump out enough water to empty pipe of water that may have been in pipe for some time.

b′ Uncap, fill bottle from spout of pump and recap or close container using the same technique and precautions outlined above when collecting specimens from a municipal faucet.

c′ Fill bottle or jar directly from the overflow pipe from a spring in the same way as from a municipal faucet.

d′ Use a bucket to dip water from well when a pump is not used, or from a spring when an overflow pipe is not used and fill specimen bottle using a clean funnel when available.

b. Air Sampling for the Detection of BW Agents Dispersed as Aerosols or Mists.

1′ Simple technique of exposure of Agar plates.

a′ Agar plates containing suitable media for culture of BW agents will be supplied to detection teams by the nearest regional laboratory.

b′ Agar plates would be exposed for specified intervals and at designated periods of time on the top of tall buildings or out in open spaces.

c′ Exposed Agar plates should be covered and returned promptly to designated laboratories for incubation and processing.

2′ Technique for Metal Funnel apparatus fitted with special BW filters attached to a Conical Side Arm Flask.

a′ The Hollaender and Della Valle apparatus permits a measured amount of air to be drawn through a funnel to play on Agar plates or on the new waferlike filters described by the U. S. Public Health Service on July 27, 1951. A partial vacuum is created by making suction on the side arm of the flask.

b′ The Agar plate on the special filter is removed with sterile forceps after a suitable interval of time and the latter is placed on a special pad saturated with special nutrient broth.

c′ The filter and the nutrient media pad are both wrapped up in pliofilm and placed in an inside pocket where the body heat starts the bacteria to growing while the packet is en route to the nearest BW laboratory.

3. Technique for U. S. Public Health experimental sampler equipped with 12 broth flasks.

a′ Place apparatus on a flat roof above street level. Electrical current is required to operate the vacuum apparatus required to pull atmospheric air through the apparatus.

b′ Atmospheric air is bubbled through the nutrient broth flasks one at a time for 20 minutes each. An unexplained rise in the total number of bacteria trapped in the broth from the atmospheric air would suggest possible danger of BW agents before the specific organism could be identified or an actual BW epidemic had time to develop.

c′ The new membrane filters described above may be incorporated into this type of air sampler. Such filters should permit the identification of disease producing bacteria in 15 hours instead of the four days previously required.

d′ The nutrient broth flasks and the samplers would be provided by the State Department of Health.

C. Exposed Clothing Suspected of BW Contamination

1′ Place clothing in clean tub or basin without handling with bare hands.

2′ Add enough water to cover clothing and agitate them for a few minutes with a clean stirring rod.

3′ Remove the clothing and fill a special shipping container or clean jar with the rinse water and forward to the nearest BW laboratory.

D. Clear Water Rinses from Structural Surfaces such as Buildings, Vehicles and Special Equipment.

1′ The outside of the building or exposed surfaces of vehicles or equipment should be scrubbed or swabbed down or washed by streams of clear water from buckets or hoses.

2′ Collect the clear water rinsings in suitable clean containers and forward to the BW laboratory.

E. Foods Exposed to Possible BW Contamination

1′ Milk and similar fluids with high protein and carbohydrate content.

a′ Collect specimens in either clean milk bottles and cap with clean milk bottle caps or in clean canning jars.

b′ The specimen should be refrigerated and rushed to the nearest BW laboratory.

2′ Exposed Solid Foods

a′ Collect representative surface samples of exposed food.

b′ Place specimens in clean canning jars, and if the food is perishable such as meat, fowl, fish or fresh vegetables, refrigerate if possible and forward to the BW laboratory.

F. Soil Samples

1′ Soil samples in general are not likely to be satisfactory because of the high number and variety of organisms normally present.

2′ Samples of soil suspected of being contaminated with spores of tetanus or anthrax are obtained by taking the topmost layer.

3′ These soil specimens should be placed in clean canning jars and be forwarded to the State BW Laboratory at the University of Maine.

G. Insect Specimens

1′ Collection may be made by special traps or by individual collection with gloved hands; or when the insects are on small animals, the latter can be anesthetized in a closed container and the anesthetized insects then combed from the animals' hair.

2′ Insects should not be crushed during collection and the collector should protect himself from infection, bites and contact with or ingestion of the insect excreta.

3′ Insect specimens should be placed in a dry tightly stoppered glass container for transport to a specially designated State BW Laboratory. It is usually not essential that the insect specimen be living on arrival at the laboratory.

H. Plant Specimens

1′ Plant specimens may be collected in any suitable closed glass, metal, wood or cardboard container for transportation to the plant laboratory at the University of Maine.

2′ Insect parasites on the leaves, stems or roots of the plant specimens collected should be shaken or brushed off into suitable glass containers, tightly stoppered and sent along with the plant specimen to the BW Laboratory at the University of Maine.

I. Human Excreta (Feces, urine and sputum)

1′ Collection of Feces Specimens

a′ Collect each specimen of feces in a bottle containing special fluid and provided by the State Bureau of Health.

b′ Place a small pea-sized portion of feces in the solution in the bottle using the small swab to transfer the specimen.

c′ Replace the cork stopper in the bottle and burn the swab.

d′ Mail or send the specimen to the State Bureau of Health Laboratory in Augusta or to the nearest regional BW laboratory.

2′ Collection of Urine Specimens.

a′ Collect each urine specimen in the same type of bottle as used for feces.

b′ Nearly fill the bottle with urine and replace the cork stopper—(The fluid already in the bottle should not be emptied out.)

c′ Do not mix urine and feces but use a separate bottle for each.

d′ Send specimen to the State Department of Health Laboratory or to the nearest regional BW laboratory.

3′ Collection of Sputum Specimens

a′ Early morning specimens are preferable.

b′ The special sputum container provided by the State Bureau of Health should be half filled with sputum and the cork secured.

c′ Forward specimen to the State Department of Health Laboratory or to the nearest regional BW laboratory.

J. Human and Animal Blood Specimens

1′ Human Blood for special agglutination or serological studies.

a′ Take 5 to 10 cc. of venous blood and place specimen in sterile glass blood tube to clot.

b′ Insert stopper, place in mailing container and send to the nearest BW laboratory.

2′ Animal Blood for special agglutination studies.

a′ Take specified amount of venous blood required to do tests in question and place in sterile glass blood container provided for this purpose.

b′ Insert stopper, place in mailing container and send to the Department of Agriculture Laboratories, University of Maine.

3′ Human Blood for Culture

Chart 4.—Special weapons portable shower for decontaminating of personnel.

a′ The flasks of special nutrient media and Agar plates will be furnished by the nearest regional BW laboratory or the State Department of Health Laboratory.

b′ The patient's arm will be prepared with Tincture of Iodine or other skin antiseptic, the blood sample taken in a sterile syringe and transferred by the usual sterile technique to the blood culture flasks and Agar plates.

c′ Blood culture specimens and Agar plates will be sent to the nearest BW or hospital bacteriological laboratory.

4′ Animal Blood for Culture

a′ The flasks of special nutrient media will be provided by the Department of Agriculture BW Laboratory at the University of Maine.

b′ The suspected animal is prepared in the usual fashion and the skin over the vein will be sterilized with Tincture of Iodine or other suitable skin antiseptic.

c′ The necessary blood samples will be drawn in a sterile syringe and a specified quantity of blood transferred to the culture flasks or Agar plates provided.

d′ Blood culture flasks and Agar plates will be sent to the Department of Agriculture Laboratories at the University of Maine.

MEDICAL NEWS

CALIFORNIA

Eye Foundation Lecture.—Dr. Frederick C. Cordes, clinical professor of ophthalmology, University of California Medical School, San Francisco, will deliver the fourth Estelle Doheny Eye Foundation lecture at 8 p. m., Nov. 5, in the Los Angeles County Medical Association building. His subject will be "Endocrine Exophthalmos—An Evaluation."

CONNECTICUT

Hospital Lectures.—The Hartford Hospital announces the following presentations in its Saturday morning 11 o'clock series:

Nov. 7, Perrin H. Long, Brooklyn, Abuses and Uses of Antibiotics.
Nov. 14, C. Lee Buxton, New York, Sterility.
Nov. 21, Samuel Proger, Boston, Cardiovascular Disease.
Nov 28, Renato A. Ricca, Glastonbury, Problems in RBC Permeability.

ILLINOIS

Psychiatric Lectures.—In its series on treatment in psychiatry, the North Shore Health Resort (225 Sheridan Road, Winnetka) offers a lecture, "What Is Psychoanalysis?" by Dr. Marc H. Hollender, assistant professor of psychiatry, University of Illinois College of Medicine, Chicago, on Nov. 4, 8 p. m., at the health resort.

Typhoid Problem.—According to a report by Dr. Roland R. Cross, Springfield, director of the state department of public health, up to Sept. 26 a total of 44 cases of typhoid had been reported in the state, compared with 30 cases in the corresponding period of 1952. Of those 44 cases, 13 were from Chicago and 31 from downstate. Most cases of typhoid occurring in Illinois were said to be traceable to personal contact or to the handling of food by apparently healthy carriers.

Chicago

Jaffe Lecture.—Dr. Paul E. Steiner, Chicago, will present the fifth Richard F. Jaffe memorial lecture before the Institute of Medicine of Chicago at the Palmer House on Nov. 2. His subject will be "Ideological Factors in Cancers as Revealed by Ethnic and Geographical Studies."

Lectures on Medical History.—The Chicago Medical School, 710 S. Wolcott Ave., announces that the following lectures in its series, "Introduction to the History of Medicine," will be given in Amphitheater A at 12:30 p. m.:

Nov. 3, Oriental Medicine, Ilza Veith, Ph.D.
Nov. 10, Medieval Medicine, Abraham Levinson.
Nov. 17, Medicine of the Sixteenth Century, Barry J. Anson, Ph.D.
Nov. 24, American Medicine, David J. Davis.

Society News.—The following program will be presented at the meeting of the North Side branch of the Chicago Medical Society in the Drake Hotel, 8 p. m. Nov. 3:

Telangiectasis of the Gastrointestinal Tract with Massive Hemorrhage, Leo L. Hardt and Samuel A. Levinson.
Treatment of Rheumatoid Arthritis, Max M. Montgomery.
Lower Back Pain in Older People, Fremont A. Chandler.
Benign Pancreatic Disease, Charles B. Puestow.
Electrolyte Metabolism in the Pre- and Postoperative Periods, Walter G. Maddock.
Anesthesia in the Elderly Patient, Lloyd A. Gittelson.
Diagnosis of True Posterior Infarction by Scapular Leads, Jack Williams.

A fellowship gathering at 5:30 p. m. will precede dinner. For reservations, call CEntral 6-7764.

MARYLAND

Lecture on Carcinoma of Colon.—The Dr. Julius Friedenwald memorial lecture will be given by Dr. Richard K. Gilchrist, professor of surgery, University of Illinois College of Medicine, Chicago, Nov. 5, 8:30 p. m., at the University of Maryland School of Medicine and College of Physicians and Surgeons (Chemical Hall—Main Building, N. E. corner of Lombard and Greene streets, Baltimore). Dr. Gilchrist will discuss "The Principles in Surgical Treatment of Carcinoma of the Colon."

Closed Circuit TV Program.—A closed TV demonstration sponsored jointly by the University of Maryland School of Medicine, the Baltimore City Medical Society, and the Maryland Academy of General Practice, will be held Nov. 5. Patterned after a previous telecast held in 1952, the clinical demonstrations will originate in the operating rooms and clinics of the University Hospital and will be carried through the facilities of WBAL-TV by closed circuit to an audience of physicians in both the Gordon Wilson Hall of the University Hospital, Baltimore, and the Osler Hall of the Medical and Chirurgical Faculty, 1211 Cathedral St. (meeting place of the Baltimore City Medical Society). A double circuit return wire will offer the audience an opportunity to ask direct questions of the clinical demonstrator. The program will start at 1 p. m., after a preliminary luncheon at 12 noon that will be served at the University Hospital and at Osler Hall, and will include clinicopathological conferences, pediatric clinics, an operative clinic, and a gynecologic clinic. Presentations will be made by members of the staffs of the University of Maryland and the Johns Hopkins University schools of medicine. Financial sponsorship has been given by the Read Drug and Chemical Company. All members of the Medical and Chirurgical Faculty of Maryland are cordially invited to attend the full meeting, luncheon included.

MASSACHUSETTS

Lecture on Congestive Failure.—The Boston University chapter of Alpha Omega Alpha will sponsor a lecture at 5 p. m. Nov. 5 in the main lecture room, Building A, Boston University School of Medicine, 80 East Concord St. Dr. Harry Gold, professor of clinical pharmacology, Cornell University Medical College, New York, will discuss "The Management of Congestive Failure."

MICHIGAN

Television Course for Parents.—The University of Michigan Medical School, Ann Arbor, announces the following television programs for November:

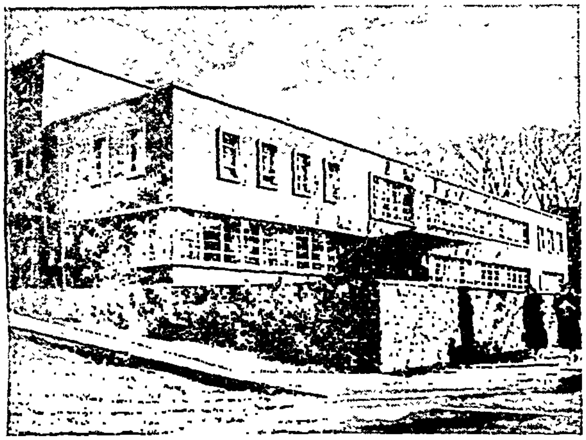
Nov. 1, Prevention of Disease, Ernest H. Watson, associate professor of pediatrics and communicable diseases.
Nov. 8, Prevention of Childhood Injuries, Harry A. Towsley, associate professor of pediatrics and communicable diseases.
Nov. 15, Your Child's Stature, Sylvester J. O'Connor, assistant professor of surgery.
Nov. 22, Your Child's Sight, F. Bruce Fralick, professor of ophthalmology.
Nov. 29, Your Child's Hearing, Albert C. Furstenberg, dean of medical school.

Personal.—Dr. William H. Beierwaltes, associate professor of internal medicine, University of Michigan Medical School, Ann Arbor, has been named the Saginaw High School distinguished alumnus of the year. At the age of 36, he is the youngest Saginaw alumnus to be so honored.——Dr. J. Marion Bryant, recently affiliated with the University of Michigan Hospital at Ann Arbor, has been appointed assistant professor of medicine, New York University Post Graduate Medical School, and has been placed in charge of inpatient cardiology, 4th medical division, Bellevue Hospital.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

NEW YORK

New Special Education Building.—The $400,000, two story special education building shown in the figure was recently dedicated at Syracuse University. It was built as a research and service center. Among the many rooms are two soundproofed "floating" rooms, which, completely isolated from the remainder of the building, rest on springs. From adjacent control rooms operators can create in the rooms practically any sound that the ear can experience. One room is used to evaluate the hearing of infants and for electroencephalographic research; the other is for hearing aid evaluation and fitting. One-way glass is employed on the second floor to divide an observation room from a laboratory in which therapists can work with preschool children, mongoloid children, or deaf children. A room in which emotionally disturbed children can receive therapy is so constructed that the child can be as aggressive as he wishes in expressing his problems—even to spattering paint or pouring gallons of water on the floor—without harming the room or the building. Other rooms of special interest are the 13 individual speech therapy rooms, a speech and phonetics laboratory, and a three room medical diagnostic suite. Among the research projects in progress are a comparative study of the speech and breathing coordination of cerebral palsied and normal children, studies on perception of epileptic and of cerebral palsied children, attitudes of cardiac children, the relative efficiency of hearing aids under different situations, skin galvanometry with children under the age of 2, a comparison of various lipreading tests, and a study to determine whether better diagnostic characteristics can be obtained for differentiation of deafness, mental retardation, and aphasia. In the building is the hearing and speech center, recently renamed in honor of Dr. Gordon D. Hoople, its medical director. Dr. Hoople, who is now professor emeritus of otolaryngology at the university, is chairman of the Advisory Committee on Audiometers and Hearing Aids, A. M. A. Council on Physical Medicine and Rehabilitation.



Special Education Building, Syracuse University.

New York City

Williams Memorial Lecture.—The New York Academy of Medicine announces that the Linsley R. Williams memorial lecture, "The Application of Physics to Medicine," will be delivered at 8:30 p. m., Nov. 4, by Norbert Wiener, Ph.D., professor of mathematics, Massachusetts Institute of Technology, Cambridge.

Lecture on Poliomyelitis.—The Mount Sinai Hospital of New York announces the 11th Bela Schick lecture, which will be held in the Blumenthal Auditorium (entrances: through the hospital gardens, Fifth Ave. at 99th St.), Nov. 6, 8:30 p. m. Dr. Gregory Shwartzman, director, department of microbiology, the Mount Sinai Hospital, and professor of microbiology, Columbia University College of Physicians and Surgeons, will discuss "New Aspects of Pathogenesis of Experimental Poliomyelitis."

Lectures on Mental Health.—The New York Academy of Medicine (2 E. 103rd St.) will present two lectures on mental health under the A. Walter Suiter lectureship, Nov. 5 at 8:30 p. m. Dr. John C. Whitehorn, Henry Phipps Professor of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, will discuss "The Acquiring and Imparting of Mental Health," and Dr. Frederick C. Redlich, professor of psychiatry, Yale University School of Medicine, New Haven, Conn., will have as his subject, "The Influence of Environment on Mental Health."

Lectures for Laymen.—The New York Academy of Medicine announces the 19th series of free lectures to the laity. Presentations will be made at the academy (2 E. 103rd St.); no admission tickets are required. The theme, "The Reciprocal Relations Between Medicine and the Other Disciplines," will be developed as follows:

Nov. 4, Application of Physics to Medicine, Norbert Wiener, Ph.D., professor of mathematics, Massachusetts Institute of Technology, Cambridge; presiding chairman, Dr. Frank J. McGowan.

Nov. 18, Relation of Electrochemistry to Medicine, Theodore Shedlovsky, Ph.D., associate member of the Rockefeller Institute; presiding chairman, Dr. Thomas M. Rivers.

Dec. 2, Practice of Psychiatry-Past and Present, Dr. Clarence P. Oberndorf, clinical professor of psychiatry, Columbia University College of Physicians and Surgeons; presiding chairman, Dr. M. Ralph Kaufman.

Jan. 6, 1954, Bearing of Anthropology Upon Medicine, Benjamin D. Paul, Ph.D., Harvard School of Public Health, Boston; presiding chairman, Dr. Paul Fejos.

Jan. 27, Where Law and Medicine Meet, David W. Peck, LL.D., presiding justice, Appellate Division, N. Y. Supreme Court; presiding chairman, Dr. Howard R. Craig.

Feb. 3, Medicine and Art, Mr. A. Hyatt Mayor, curator of prints, Metropolitan Museum of Art; presiding chairman, Dr. Jerome P. Webster.

Meeting on Tuberculosis.—"The Citizen's Part in Tuberculosis and Health Activities" will be the theme of the annual conference of the New York Tuberculosis and Health Association, Nov. 5 at the Hotel Statler, 7th Ave. at 32nd St. Dr. Wilson G. Smillie will preside over the general session, which will open at 9:45 a. m. in the Georgian Room with a presentation by Dr. Herbert R. Edwards, entitled "Next Steps to Be Taken." This will be followed by "The City Takes a Step," in which Dr. Arthur B. Robins will discuss the new interdepartmental coordinated treatment program. At 12:45 p. m. "Personnel—the Key to Improving Health Conditions" will be presented by Dr. Willard C. Rappleye and "The Citizen's Part" by Henry T. Heald, LL.D., Chicago. Dr. Leona Baumgartner will serve as chairman for the panel and audience discussion at 3 p. m. in the Georgian Room when the available health resources at home, at work, and in neighborhoods will be examined. The panel includes Drs. John A. P. Millet and Leo Price.

OHIO

Symposium on Surgery of the Hand.—This postgraduate symposium will be presented by St. Luke's Hospital, Cleveland, Nov. 5-7 at Prentiss Auditorium. Subjects to be considered include form and function, injury, general techniques, and special interests. Dr. Don L. Eyler, Nashville, Tenn., will present two films: Functional Anatomy Film, Thursday, 9:15-9:45 a. m., and Markee Film, Functional Anatomy, Friday, 9:45-10 a. m. Dr. Harvey S. Allen, Chicago, will speak on farm hand injuries, Thursday, 2:30-3 p. m. and will deliver the Rollett A. Cardon memorial lecture at the dinner Thursday, 6-8 p. m. On Friday, 11:10-11:40 a. m., Dr. Francis E. Nulsen, Philadelphia, will discuss "Injury to the Nerves." Friday, 4-5 p. m., there will be a plastic reconstruction round robin. The Friday evening session, 8-10:30 p. m., will include a round robin on dystrophy.

OREGON

Academy Meeting.—Dr. Carl V. Moore, professor of medicine, Washington University School of Medicine, St. Louis, will be guest speaker of the Portland Academy of Medicine at its meeting in the University of Oregon Medical School auditorium, Nov. 5-6, 8-9:30 p. m. His subjects will be "Iron Metabolism and the Pathogenesis of Iron Deficiency Anemias" and "Platelets, Platelet Antibodies, Platelet Types and Thrombocytopenic Purpura."

PENNSYLVANIA

Mobile Physiotherapy Unit.—The Beneficial Saving Fund of Philadelphia has presented to the Eastern Pennsylvania chapter of the Arthritis and Rheumatism Foundation a fully equipped mobile physiotherapy unit for the home treatment of arthritic patients. A trained physiotherapist will supervise the treatments rendered from the mobile unit.

Philadelphia

Alvarenga Prize Lecture.—At the joint meeting of the College of Physicians of Philadelphia and the Philadelphia County Medical Society at the hall of the College of Physicians, 19 S. 22nd St., Nov. 4, 8:30 p. m., Dr. Francis D. Moore, Mosely Professor of Surgery, Harvard Medical School, Boston, will deliver the Alvarenga prize lecture, "Recovery from Injury: An Endocrine Sequence."

WASHINGTON

Symposium on Heart Disease.—The Washington State Heart Association and the Washington State Department of Health will present the fifth annual symposium on heart disease at the University of Washington Medical School, Seattle, Nov. 6-7. Guest speakers will be Drs. Herrman L. Blumgart and David D. Rutstein, Boston, Howard B. Burchell, Rochester, Minn., and Paul Wood, London, England. Subjects scheduled for discussion include: congenital and acquired valvular heart lesions amenable to surgery, pulmonary hypertension in congenital heart disease, treatment of intractable congestive failure, and rheumatic fever. There will be no registration fee. The symposium is the equivalent of nine hours of formal postgraduate training for members of the Academy of General Practice.

WEST VIRGINIA

Meeting of Heart Association.—The annual meeting of the West Virginia Heart Association will be held at the Daniel Boone Hotel, Charleston, Nov. 6, under the presidency of Dr. W. Frederick Richmond, Beckley. The meeting will open with a subscription luncheon at 12:30 p. m. Drs. Paul D. White, Boston, and T. Duckett Jones, New York, will be guest speakers at the afternoon session, which will have as its theme, "Rheumatic Fever and Rheumatic Heart Disease, Medical and Surgical." A social hour at 5:30 p. m. will precede the annual banquet for which Dr. Jones will be guest speaker. Dr. White will present "The Changing Scene—New Hope for Hearts" at the open meeting, 8:30 p. m.

WISCONSIN

Society News.—The Milwaukee Oto-Ophthalmic Society has elected Dr. Gerhard D. Straus, president, Dr. Erwin E. Grossman, vice-president, and Dr. Donald T. Hughson, secretary-treasurer.

Dearholt Days.—The Wisconsin Anti-Tuberculosis Association, in cooperation with the Marquette University School of Medicine, Milwaukee, University of Wisconsin Medical School, Dane County Medical Society, Wisconsin Trudeau Society, and the VA Hospital, Madison, will sponsor the annual Dearholt Days, Nov. 9-10, in Milwaukee and Madison. William H. Feldman, D.V.M., professor of comparative pathology, University of Minnesota Graduate School, Minneapolis, will present "Anti-Tuberculosis Properties of Substances Considered for Therapeusis: Their Detection and Experimental Evaluation," and Dr. William B. Tucker, clinical associate professor of medicine, University of Minnesota, will discuss "The Accurate Evaluation of Therapeutic Procedures in Clinical Medicine: Cooperative Studies in the Chemotherapy of Tuberculosis." Dr. John S. Hirschboeck, dean, Marquette University School of Medicine, will preside at the Monday afternoon session, 3 p. m. Nov. 9, in the auditorium at 561 N. 15th St. The Tuesday session will be held in the auditorium, Service Memorial Institute, University of Wisconsin, Madison, at 3 p. m., Dr. William S. Middleton, dean of the medical school, presiding. Tuesday, 8 p. m., Dr. Samuel L. Chase, Madison, president, Dane County Medical Society, will preside at a session in the Veterans Administration Hospital auditorium, 2500 Overlook Terrace, Madison. Dr. Feldman will have as his subject, "Chemotherapy of Infectious Disease—A Two-Edged Sword," and Dr. Tucker will speak on the subject, "Modern Drug Treatment of Pulmonary Tuberculosis."

GENERAL

New England Postgraduate Assembly.—The New England Postgraduate Assembly, which will meet at the Hotel Statler, Boston, Nov. 2-4, will offer numerous clinics and panels and, as a new feature, clinical pathological conferences.

Meeting on Arteriosclerosis.—The American Society for the Study of Arteriosclerosis will hold its annual meeting at the Knickerbocker Hotel, Chicago, Nov. 1-2. Dr. Nelson W. Barker, Rochester, Minn., will deliver the presidential address Sunday at 2:20 p. m. The principal address by invitation will be given Sunday, 10 a. m., by Dr. James Watt, Director, National Heart Institute, National Institutes of Health, U. S. Public Health Service, Bethesda, Md., whose topic will be "Arteriosclerosis and Epidemiology." After 35 presentations the sessions will conclude with a demonstration on chromatographic partition of serum proteins, protein-bound lipids and protein-bound carbohydrates in rabbits, before, during, and after cholesterol feeding, by Dr. O. J. Pollak and George Chubaty, Kent General Hospital, Dover, Del.

Academy of Psychosomatic Medicine.—At a recent meeting in New York, the American Academy of Psychosomatic Medicine was founded "to advance the scientific knowledge and practice of those aspects of medicine which relate to the interaction of mind, body, and environment, by means of study, laboratory and clinical research, meetings, and discussions in cooperation with other workers in these and related fields." Membership will consist of chapter fellows (those who enrolled at the organizational meeting) and founding fellows (those who join before Jan. 1, 1954). Requirements for membership can be obtained from the secretary, Dr. Ethan Allan Brown, 75 Bay State Road, Boston. The other officers elected at the founding meeting included Dr. William Kaufman, Bridgeport, Conn., president, Dr. Bernard B. Raginsky, Montreal, vice-president, and Dr. Alfred J. Cantor, Flushing, N. Y., treasurer. The first scientific meeting will be held in New York in June, 1954.

Meeting of Pathologists.—The College of American Pathologists (North Central region) and the Minnesota Society of Clinical Pathologists will hold a joint meeting at the Mayo Clinic and Foundation, Rochester, Minn., Nov. 6-7. On both days demonstrations in surgical pathology will be conducted, 9-10 a. m. A program on clinical pathology will be presented Friday, 10:30 a. m. to 12 noon, and a program on surgical pathology, Saturday at the same time. Friday afternoon will be devoted to a tour and demonstrations of the clinical laboratories (1914 building) and medical sciences building. The business meeting of the Minnesota Society of Clinical Pathologists will follow the dinner at the Rochester Country Club, 6:30 p. m. Friday, at which Dr. William V. Knoll, Duluth, Minn., will serve as toastmaster. Wives of visiting men are invited to the dinner and to a luncheon Saturday, 12:15-1:30 p. m., at the Mayo Foundation House (compliments of the Mayo Clinic and Foundation). After the luncheon a program on pathologic anatomy will be presented.

Program on Sterility.—The American Society for the Study of Sterility will hold a regional open meeting at Deep Well Ranch, Palm Springs, Calif., Nov. 6-8. The sessions will open Friday, 8-10:30 p. m., to consider medicosociological aspects of infertility. Dr. William B. Thompson, Los Angeles, will serve as moderator for an adoption panel. Paul Popenoe, Los Angeles, will speak on sexual problems and their relation to infertility. The session will end with an artificial insemination panel, in which Dr. Frances E. Shields, Monterey, Calif., will consider the clinical aspects and Dr. John O. Haman, San

Francisco, legal problems arising from artificial insemination. The afternoon session will include: (1) consideration of diagnostic measures in infertility; (2) a panel on the question of surgery in infertility; (3) prevention of infertility; and (4) common features in the processes of fertilization and immunity. The closing session Sunday, 10 a. m. to 12:30 p. m., will provide the following program:

An Adequate Program for Routine Investigation of the Sterile Couple, Richard R. Gratton, San Francisco.
Clinical Research Problems in Long-Standing Infertility Cases, Edward T. Tyler, Los Angeles.
Use of Testosterone Rebound Therapy in Male Infertility, M. James Whitelaw, San Francisco.
Clinical Use of Irradiation in Sterility Due to Ovarian Deficiency, Sheldon A. Payne, Los Angeles.
Genetic Aspects of Radiation Therapy, Edward B. Lewis, Ph.D., Pasadena, Calif.
Nutrition in Infertility, Samuel J. Glass, Los Angeles.

Registration is open to interested physicians and research workers; wives are cordially invited. Registration fee, $5, should be sent to Dr. Edward T. Tyler, 10911 Weyburn Ave., Los Angeles 24, or to Dr. John O. Haman, 490 Post St., San Francisco. There is no registration fee for hospital residents, interns, and members of the armed forces.

Cancer Society Meeting in New York.—The American Cancer Society will hold its annual meeting at the Hotel Commodore, New York, Nov. 3-4. "Cancer of the Lung: A Critical Evaluation" is the theme of the scientific session, which will open Tuesday with a paper, "Is Lung Cancer on the Increase—Evaluation of Present Day Evidence" by Harold F. Dorn, Ph.D., National Institutes of Health, Bethesda, Md. "Etiology: Occupational and Environmental Aspects" will next be considered in the following presentations: (1) The Place of Tobacco in the Etiology of Lung Cancer (Dr. Ernst L. Wynder and E. Cuyler Hammond, Sc.D., New York; (2) The Current Status of Air Pollution Studies in the Etiology of Lung Cancer (Dr. Paul Kotin, Los Angeles); (3) The Experimental Production of Lung Tumors (Howard B. Andervont, ScD., Bethesda, Md., and Dr. Harry S. N. Greene, New Haven, Conn.); (4) Potential Occupational Factors (Dr. William E. Smith, New York); and (5) The Geographic Considerations in the Lung Cancer Problem (Dr. Harold L. Stewart, Bethesda, Md.).

The detection aspects of control will be presented in the following papers:

Dividends and Defects of the Mass Survey Method in Detecting Lung Cancer, Lewis W. Guiss, Los Angeles.
Lung Cancer Yield in Mass Urban Chest X-Ray Series, Robert J. Anderson, Washington, D. C.
Public Education, Charles S. Cameron, New York.

In a presentation on diagnosis, Dr. Richard H. Overholt, Boston, will have as his subject, "The Direct Approach to Shadow and Substance." Techniques of diagnosis will be discussed by Dr. Leo G. Rigler, Minneapolis (Routine Chest Films in the Detection of Early Lung Cancer with Particular Attention to the Importance of Comparative Studies); Dr. Eugene P. Pendergrass, Philadelphia (Potential Application of Supervoltage Roentgen Rays in the Detection of Early Pulmonary Lesions); Dr. Peter A. Herbut, Philadelphia (Practical Applications of Exfoliative Cytology in the Early Diagnosis of Lung Cancer); and Dr. William F. Rienhoff, Baltimore, (The Value of Exploratory Thoracotomy in the Diagnosis of Unknown Pulmonary Lesions). The following papers on pathology will be presented:

Cancer of the Lung: One Disease?, Evarts A. Graham, St. Louis.
Biological Behavior of Carcinomas of the Lung as Influenced by Their Cellular Structures, Bela Halpert, Houston, Texas.
Multiple Foci of Origin of Lung Cancer, Lauren V. Ackerman, St. Louis.
Relationship of Pulmonary Adenomatosis to Cancer of the Lung, Hans F. Smetana, Washington, D. C.

The sessions will conclude with presentations on treatment:

The Operation to be Undertaken, Edward D. Churchill, Boston.
Results of Radical Pneumonectomy in Cancer of the Lung, John L. Pool, New York.
Surgical Palliation in Advanced Lung Cancer, Alton Ochsner, New Orleans.
Newer Modalities of Roentgen Rays in the Treatment of Cancer of the Lung, Hugh F. Hare, Los Angeles, and Milford D. Schulz, Boston.
Treatment of Advanced Lung Cancer by Chemical Methods, David A. Karnofsky, New York.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories, and possessions in the weeks ended as indicated:

	Oct. 17, 1953

FOREIGN

Courses on Hepatic Biopsy and Laparoscopy.—A second course on hepatic biopsy puncture and a first course on laparoscopy will be given Nov. 2-14 in the Servicio de Patología Digestiva of the Hospital de la Santa Cruz y San Pablo in Barcelona, Spain. Each course is limited to 10 scholars. The fee is 500 pesetas, and details are obtainable from Administración del Hospital de la Santa Cruz y San Pablo.

Nelson Laboratory in Vienna.—A new Nelson laboratory was recently opened in Vienna, in the buildings in which Prof. Rudolf Müller (best remembered for the Müller-Oppenheim reaction) did his pioneer work in venereal serology. Because of the difficulty in preparing adequate amounts of the materials necessary for the Nelson test, only a small number of Nelson laboratories are now functioning in Europe and North and South America.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Arkansas:* *Examination.* Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

Colorado:* *Examination.* Denver, Dec. 15-16. Final date for filing application is Nov. 14. Executive Secretary, Miss Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Connecticut:* *Regular. Examination.* New Haven, Nov. 10-11. Reciprocity actions are taken continuously. Secretary to the Board, Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic.* Derby, Nov. 10-11. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

Florida:* *Examination.* Jacksonville, Nov 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana

Hawaii: Honolulu, Jan. 11-14. *Examination.* Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Iowa:* *Examination.* Des Moines, Dec. 7-9. Sec., Dr. M. A. Royal, 506 Fleming Bldg.. Des Moines.

Kansas: Topeka, Dec. 9-10. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 7-9. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville.

Maine: Portland, Nov. 12-13. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination.* Baltimore, Dec. 8-11. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St, Baltimore 1.

Mississippi: *Reciprocity.* Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

Nebraska:* *Examination.* Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

North Dakota. *Examination.* Grand Forks, Jan. 6-9, 1954. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, Dec. 17-19. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oklahoma:* *Examination.* Oklahoma City, June 9-10. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Pennsylvania: *Examination.* Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

South Dakota:* *Examination.* Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Texas: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed 30 days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination and Reciprocity.* Salt Lake City, Nov. 17. Director, Mr. Frank E. Lees, 314 State Capitol, Salt Lake City 1.

Vermont: *Examination.* Burlington, Feb. 1954. Sec., Dr. F. J. Lawliss, Richford.

Virginia: *Examination.* Richmond, Dec. 3-5. *Reciprocity.* Richmond, Dec. 2. Address: Board of Medical Examiners, 631 First St. S.W., Roanoke.

Virgin Islands: *Examination.* Charlotte Amalie, Nov. 11-12. Sec., Dr. Earle M. Rice, Box 90, St. Thomas.

Wisconsin:* *Examination and Reciprocity.* Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Florida: *Examination.* Gainesville, Nov. 7. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Oklahoma: *Examination.* Oklahoma City, April 16-17. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Dec. 5. Sec., Dr. Charles D. Byrne, University of Oregon, Eugene. (Examinations during 1954 will be held in Portland on March 6, June 5, Sept. 11 and Dec. 4.)

South Dakota: *Examination.* Vermillion, Dec. 4-5. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Wisconsin: *Examination.* Milwaukee, Dec. 5. Final date for filing application is Nov. 27. Madison, April 3. Final date for filing application is March 26. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 5-10. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland 1, Secretary.

American Academy of Obstetrics and Gynecology, Netherland Plaza Hotel, Cincinnati, Dec. 14-16. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago 3, Secretary.

American Academy of Tropical Medicine, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. E. Harold Hinman, University of Puerto Rico, School of Medicine, San Juan 22, P. R., Secretary.

American Cancer Society, New York, Nov. 2-6. Dr. Charles S. Cameron, 47 Beaver St., New York 4, Medical Director.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Nov. 2-4. Dr. Marshall N. Fulton, 124 Waterman St., Providence 6, R. I., Secretary.

American College of Cardiology, Hotel Statler, Cleveland, Ohio, Nov. 6-7. Dr. Philip Reichert, 480 Park Ave., New York 22, Secretary.

American Public Health Association, Hotel New Yorker and Hotel Statler, New York, Nov. 9-13. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel New Yorker, New York, Nov. 9-13. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society for the Study of Arteriosclerosis, Hotel Knickerbocker, Chicago, Nov. 1-2. Dr. O. J. Pollak, P. O. Box 228, Dover, Del., Secretary.

American Society of Tropical Medicine and Hygiene, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. John E. Larsh Jr., University of North Carolina, School of Public Health, Chapel Hill, N. C., Secretary.

Association of Military Surgeons of the United States, Hotel Statler, Washington, D. C., Nov. 8-11. Dr. R. R. Sayers, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 11-12. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Association of State and Territorial Health Offcers, Washington Hotel, Washington, D. C., Nov. 4-7. Dr. John D. Porterfield, 306 Ohio Depts. Bldg., Columbus 15, Ohio, Secretary.

Central Association of Obstetricians and Gynecologists, The Shamrock, Houston, Texas, Nov. 5-7. Dr. Harold L. Gainey, Suite 602, 116 South Michigan Ave., Chicago 3, Secretary.

Conference of Public Health Veterinarians, Hotel New Yorker, New York, Nov. 9. Dr. James Lieberman, U. S. Public Health Service, Washington 25, D. C., Secretary.

Congress of Neurological Surgeons, Roosevelt Hotel, New Orleans, Nov. 12-14. Dr. B. W. Cannon, 1092 Madison Ave., Memphis, Tenn., Secretary.

Interstate Post Graduate Medical Association of North America, Palmer House, Chicago, Nov. 2-5. Dr. E. R. Schmidt, 1300 University Ave, Madison 5, Wisconsin, Secretary.

Inter-Society Cytology Council, Philadelphia, Nov. 19-20. Dr. Paul F. Fletcher, 634 North Grand Blvd., St. Louis 3, Secretary.

National Association for Mental Health, Hotel Carter, Cleveland, Oct. 31-Nov. 2. Dr. George S. Stevenson, 1790 Broadway, New York 19, Medical Director.

National Society for Crippled Children and Adults, Palmer House, Chicago, Nov. 12-14. Mr. Lawrence J. Linck, 11 South LaSalle St., Chicago 3, Secretary.

National Society for the Prevention of Blindness, New York, Dec. 18. Dr. Franklin M. Foote, 1790 Broadway, New York 19, Executive Director.

North Pacific Surgical Association, Victoria, B. C., Nov. 20-21. Dr. John A. Duncan, 509 Olive Way, Seattle, Secretary.

Pacific Northwest Society of Pathologists, Eugene, Oregon, Nov. 6-7. Dr. John L. Whitaker, 315 South K St., Tacoma 3, Wash., Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 13-18. Dr. Donald S. Childs, 713 East Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

- Michigan, H. H. Rackham Auditorium, Ann Arbor, Dec. 5. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Governor.
- Midwest—Ill., Ind., Iowa, Minn., Wis.—Hotel Schroeder, Milwaukee, Nov. 21. Dr Francis D. Murphy, 536 West Wisconsin Ave., Milwaukee 3, Chairman.
- New Jersey, Trenton, Nov. 4. Dr. Edward C. Klein Jr., 73 Lincoln Park, Newark 2, Governor.
- North Carolina, Chapel Hill, Dec. 3. Dr. Elbert L. Persons, Duke Hospital, Durham, Governor.

Regional Meetings, American Rheumatism Association:

- Ohio and Western Pennsylvania, Mayflower Hotel, Akron, Ohio, Nov. 11. Dr. Roger Q. Davis, 1405 Goodyear Blvd., Akron 5, Ohio, Chairman.

Southern California Psychiatric Society, Hotel Statler, Los Angeles, Nov. 14. Dr. Jerome M. Kummer, P. O. Box 305, Santa Monica, Secretary.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 8-10. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

Western Surgical Association, The Drake, Chicago, Dec. 3-5. Dr. Michael Mason, 154 East Erie St., Chicago 11, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

British Medical Association, Glasgow, Scotland, July 1-9, 1954. Dr. A. MaCrae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Conference of International Union Against Tuberculosis, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

Congress of International Association for the Prevention of Blindness, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

Congress of International Society of Surgery, Paris, France, May 21-22, 1954. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress of Clinical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A. Moore, Washington University School of Medicine, St. Louis 10, Missouri, U. S. A., Chairman, Committee on Arrangements.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hematology, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6ᵉ, France, Secretary.

International Congress of the History of Medicine, Rome and Salerno, Italy, Sept. 13-20, 1954. For information write: Segreteria XIV Congresso Internazionale di Storia della Medicina, Instituto di Storia della Medicine, Citta Universitaria, Rome, Italy.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni Venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of Industrial Medicine, Naples, Italy, Sept. 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Policlinico, Naples, Italy, Chairman, Organizing Committee.

International Congress of Internal Medicine, Stockholm, Sweden, Sept. 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, Sweden, Secretary-General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

International Congress of Nutrition, Amsterdam, Netherlands, Sept. 14-18, 1954. For information write: Dr. M. van Eekelen, Centraal Instituut voor Voedingsonderzoek T.N.O., 61 Catharynesingel, Utrecht, Netherlands.

International Congress on Obstetrics and Gynecology, Geneva, Switzerland, July 26-31, 1954. Dr H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

International Congress of Ophthalmology, University of Montreal and McGill University, Montreal, Canada, Sept. 10-11, 1954, and Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 12-17, 1954. Dr. William L. Benedict, 100 First Avenue Building, Rochester, Minnesota, U. S. A., Secretary-General.

International Congress of Orthopedic Surgery and Traumatology, Berne, Switzerland, Aug. 30-Sept. 3, 1954. For information write: Professor M. Dubois, Isle-Hospital, Berne, Switzerland.

International Congress of Psychology, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N. J., U. S. A.

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Poliomyelitis Congress, Rome, Italy, Sept. 6-10, 1954. Mr. Stanley E. Henwood, 120 Broadway, New York 5, N. Y., U. S. A., Executive Secretary.

International Society of Blood Transfusion, Paris, France, Sept. 12-19, 1954. For information write: Colonel Julliard, Societe Internationale de Transfusion Sanguine, 53 Boulevard Diderot, Paris 12ᵉ, France.

International Society for Cell Biology, Leiden, Netherlands, Sept. 2-9, 1954. Professor Peter J. Gaillard, University of Leiden, Leiden, Netherlands, Secretary.

International Society of Geographical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Professor Fred C. Roulet, Hebelstrasse 24, Basle, Switzerland, Secretary-General.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geofroix, Colombes (Seine) France.

Latin American Congress of Otorhinolaryngology, Caracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro, Medico, Caracas, Venezuela, Secretary-General.

Pacific Science Congress, Quezon City and Manila, Philippines, Nov. 16-28. Dr. Patrocinio Valenzuela, College of Pharmacy, University of the Philippines, Quezon City, Philippines, Secretary-General.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, Mexico, D.F., Mexico, Feb. 28-March 4, 1954. Dr. Pedro Hernandez Gonzalo, 8 No. 358, Vedado, Havana, Cuba, General Secretary.

Pan American Medical Association, International Medical Cruise Congress, S. S. Nieuw Amsterdam, Jan. 6-22, 1954. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, N. Y., U. S. A., Executive Director.

Pan-Pacific Surgical Congress, Honolulu, Hawaii, Oct. 7-18, 1954. Dr. F. J. Pinkerton, Suite 7, Young Bldg., Honolulu 13, Hawaii, Director General.

Persian Gulf Medical Society, Dhahran, Saudi Arabia, Dec. 7-8. Dr. N. J. Conan Jr., Department of Internal Medicine, Arabian American Oil Company, Dhahran, Saudi Arabia, Secretary.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

South American Congress of Angiology, Sao Paulo, Brazil, July 1954. For information write: Dr. Rubens Carlos Mayall, Rua Senador Vergueiro 73, Rio de Janeiro, Brazil, S. A.

World Congress of Cardiology, Washington, D. C., and Bethesda, Md., U. S. A., Sept. 12-17, 1954. Dr. L. W. Gorham, 44 East 23d St., New York 10, N. Y., U. S. A., Secretary-General.

World Congress of International Society for the Welfare of Cripples, The Hague, Netherlands, Sept. 13-17, 1954. For information write: D. C. Schaap, Centrale Vereniging, Apeldoorschweg 51, Arnhem, Netherlands.

World Federation of Occupational Therapists, Edinburgh, Scotland, August 17, 1954.

World Medical Association, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

DEATHS

Smith, Troy, Chicago; Indiana University School of Medicine, Indianapolis, 1917; appointed a lieutenant in the medical reserve corps of the U. S. Army during World War I; received a citation for examining draftees during World War II; member of the Interstate Post Graduate Assembly of North America and the National Medical Association; treasurer of the Cook County Physicians Association; senior attending physician at Provident Hospital, where he died Sept. 21, aged 62, of intestinal obstruction and general peritonitis, following operation for carcinoma of the sigmoid.

Abrams, Corydon Jackson ⊕ Spokane, Wash.; Kansas City (Mo.) Medical College, 1905; an Associate Fellow of the American Medical Association; formerly county coroner; served on the staffs of the Deaconess Hospital, St. Luke's Hospital, and Sacred Heart Hospital, where he died Sept. 7, aged 75, of heart disease.

Austin, Fred H. ⊕ Bloomington, Ind.; Cincinnati College of Medicine and Surgery, 1890; an Associate Fellow of the American Medical Association; affiliated with Bloomington Hospital; died Sept. 4, aged 83, of ruptured appendix and peritonitis.

Balsinger, William Ernest, Los Angeles; University of Pennsylvania Department of Medicine, Philadelphia, 1907; died Aug. 22, aged 70.

Barkley, A. Wray ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1901; served during World War I; following World War II received a citation from the late President Roosevelt for his work in examining draftees; died in Orange, Calif., June 27, aged 74, of cerebral thrombosis.

Bower, Ernest C., Davenport, Iowa; the Hahnemann Medical College and Hospital, Chicago, 1889; died in the Mercy Hospital Sept. 8, aged 86, of arteriosclerotic heart disease.

Brown, Columbus, Herrin, Ill.; Missouri Medical College, St. Louis, 1898; died in the Herrin Hospital Sept. 5, aged 84, of arteriosclerotic heart disease.

Bryant, Daniel John, Cleveland; Cleveland Medical College, Homeopathic, 1897; affiliated with Huron Road Hospital for many years; died in Astatula, Fla., Sept. 11, aged 80.

Bullen, Benjamin Wells Jr. ⊕ Greenwich, Conn.; Cornell University Medical College, New York, 1941; specialist certified by the American Board of Pediatrics; served during World War II; affiliated with Greenwich Hospital and the New York Hospital; found dead on the beach at Fire Island, N. Y., Sept. 1, aged 40.

Caldwell, John Ewart ⊕ Detroit; McGill University Faculty of Medicine, Montreal, Canada, 1924; member of the Industrial Medical Association; served during World Wars I and II; died Sept. 11, aged 55.

Caldwell, Robert Dennis ⊕ Lynchburg, Va.; Medical College of Virginia, Richmond, 1919; served during World War I; affiliated with Marshall Lodge Memorial, Virginia Baptist, and Lynchburg General hospitals; died Aug. 18, aged 59.

Cartmell, Harry D. ⊕ Greenville, Ill.; Northwestern University Medical School, Chicago, 1905; an Associate Fellow of the American Medical Association; at one time county coroner; died in the Mark Greer Hospital, Vandalia, Sept. 2, aged 73, of carcinoma of the prostate.

Clagett, Arthur Neville ⊕ Evanston, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; served during World War I; affiliated with Bethany Hospital in Chicago, where he died Sept. 20, aged 82, of coronary thrombosis and arteriosclerotic heart disease.

Clarkson, James A. Coleman ⊕ Lewistown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1887; member of the House of Delegates of the American Medical Association in 1928; for many years secretary of the Mifflin County Medical Society; on the staff of Lewiston Hospital, where he was formerly chief of surgery, and from 1926 to 1929 secretary of the staff; died Aug. 21, aged 93.

Cochran, Marcellus Francis, Newnan, Ga.; Vanderbilt University School of Medicine, Nashville, Tenn., 1914; died June 17, aged 60.

Cox, Henry McCall ⊕ Paducah, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1919; member of the Tennessee State Medical Association; area health officer at Shawnee Steam Plant; died July 7, aged 59, of coronary occlusion.

Dobbins, Thomas Carson, Denton, Texas; Louisville (Ky.) Medical College, 1903; formerly member of the school board; died Sept. 1, aged 74, of coronary occlusion.

Dohrmann, George ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; past president of the surgical staff of Grant Hospital; died Sept. 25, aged 76, of recurrent carcinoma of the colon.

Dye, James A., Chloe, W. Va.; Starling Medical College, Columbus, 1891; affiliated with Gordon Memorial Hospital in Spencer, where he died Sept. 20, aged 86, of cerebral hemorrhage.

Dyko, William Edward ⊕ Chicago; Chicago Medical School, 1936; affiliated with Alexian Brothers and St. Joseph's hospitals; died Sept. 26, aged 47, of coronary thrombosis and arteriosclerosis.

Engle, John Max ⊕ Portland, Ind.; Indiana University School of Medicine, Indianapolis, 1940; served overseas in the Pacific area during World War II; past president of the Jay County Medical Society; affiliated with Jay County Hospital, where he died Sept. 3, aged 37, of coronary occlusion.

Fox, Charles Moses ⊕ Chicago; Chicago College of Medicine and Surgery, 1913; fellow of the American College of Surgeons; formerly on the faculty of Loyola University School of Medicine; awarded the distinguished service cross for extraordinary heroism in action during World War I; affiliated with Oak Park (Ill.) Hospital, where he died Sept. 23, aged 73, of uremia.

Franklin, Paul Hutchins ⊕ Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1899; on the staff of the Western Pennsylvania Hospital; died Sept. 3, aged 78.

French, William Gayle ⊕ Evansville, Ind.; the Hahnemann Medical College and Hospital, Chicago, 1906; member of the National Gastroenterological Association; formerly county coroner; died Sept. 11, aged 68, of coronary thrombosis.

Froyd, Melvin Frankford, Roseburg, Ore.; Loyola University School of Medicine, Chicago, 1918; ward physician, Veterans Administration Hospital; died near Leggett, Calif., July 14, aged 62, of injuries received in an automobile accident.

Gibson, William Henry ⊕ Booneville, Ky.; Hospital College of Medicine, Louisville, 1906; secretary of the Owsley County Medical Society; served as chairman of the county board of health; president of the Farmers State Bank; died Sept. 7, aged 71.

Gray, Denver Francis ⊕ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1912; died July 29, aged 67.

Hagen, Henry Otto, New Richland, Minn.; Rush Medical College, Chicago, 1903; died in St. Peter Aug. 31, aged 76, of arteriosclerosis.

⊕ Indicates Member of the American Medical Association.

Herron, William Floyd ⊕ Aurora, Mo.; Omaha Medical College, 1901; for many years county health officer, and health officer of the city of Aurora; affiliated with Aurora Hospital, where he died Sept. 6, aged 75, of food poisoning.

High, Charles Vernell Jr., Midland, Mich.; Detroit College of Medicine and Surgery, 1914; past president of the Midland County Medical Society; found dead Aug. 20, aged 62.

Hill, Walter Coit ⊕ Cleveland; Western Reserve University Medical Department, Cleveland, 1903; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America, and the American College of Radiology; served during World War I; formerly assistant superintendent, Lakeside Hospital; died Sept. 6, aged 77, of cancer of the pancreas.

Houser, Daniel Cary ⊕ Urbana, Ohio; Starling Medical College, Columbus, 1897; past president of the Ohio State Medical Association and the Champion County Medical Society; elected councilor of the Second District Medical Society in 1925; served during World War I; member of the American Academy of General Practice; died Aug. 4, aged 86, of chronic myocarditis and arteriosclerosis.

Houston, Grant ⊕ Joliet, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1894; fellow of the American College of Surgeons; past president of the Will-Grundy Counties Medical Society; affiliated with St. Joseph's Hospital and the Silver Cross Hospital, where he died Sept. 24, aged 88, of cerebral hemorrhage.

Ikins, Ray George ⊕ Lafayette, Ind.; Indiana University School of Medicine, Indianapolis, 1919; fellow of the American College of Surgeons; served during World Wars I and II; affiliated with Lafayette Home Hospital and St. Elizabeth Hospital; died Sept. 28, aged 57, of primary mediastinal carcinoma.

Jackson, John Wagner, Fort Plain, N. Y.; University and Bellevue Hospital Medical College, New York, 1921; served during World War I; formerly on the staffs of the New York and Doctors hospitals in New York City; died Aug. 7, aged 59, of angina pectoris.

Johnson, Rezin Pritchard, Jacksonville, Ill.; Chattanooga (Tenn.) Medical College, 1897; served during World War I; formerly affiliated with the Jacksonville State Hospital; died Sept. 18, aged 81, of coronary occlusion.

Kemper, Americus Judson ⊕ Lost Creek, W. Va.; Eclectic Medical Institute, Cincinnati, 1903; an Associate Fellow of the American Medical Association; for many years county health officer; died Sept. 12, aged 80, of a heart attack.

Klein, Harry, Manasquan, N. J.; University and Bellevue Hospital Medical College, New York, 1909; died in Fitkin Memorial Hospital, Neptune, Aug. 2, aged 64, of arteriosclerotic heart disease and occlusion of the ascending aorta.

McIntosh, Arthur Merrill ⊕ Berkeley, Calif.; University of California Medical School, San Francisco, 1900; served during World War I; affiliated with Alta Bates and Herrick Memorial hospitals; died Sept. 14, aged 75, of arteriosclerosis.

Marshall, William Norman, Florence, Texas; Louisiana State University School of Medicine, New Orleans, 1948; served in the U. S. Navy from 1942 to 1946; formerly affiliated with the Veterans Administration Hospital in Big Springs; died recently, aged 31, as a result of a head injury received in an automobile accident.

Miller, James Edwin, Steubenville, Ohio; Western Pennsylvania Medical College, Pittsburgh, 1894; served in France during World War I; member of the Radiological Society of North America; for many years affiliated with Ohio Valley Hospital, where he died Sept. 1, aged 84, of carcinoma of the prostate.

Nowlin, Ralph Robert, State Sanatorium, Ark.; University of Texas School of Medicine, Galveston, 1920; member of the American Trudeau Society; at one time instructor in medicine at his alma mater; served during World War I; assistant to the medical director, Arkansas Tuberculosis Sanatorium; died Sept. 5, aged 60, of coronary thrombosis.

Reinicke, Edward Louis ⊕ Dubuque, Iowa; St. Louis College of Physicians and Surgeons, 1902; died in the Finley Hospital June 22, aged 73, of bronchogenic carcinoma and generalized arteriosclerosis.

Rogers, Walter Ferrier Jr. ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1943; certified by the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; assistant professor of medicine at his alma mater, now known as State University of New York College of Medicine; member of the American Federation of Clinical Research, American Diabetic Society, and the Endocrine Society; died Sept. 18, aged 35.

Sartor, Thomas Ryan ⊕ De Ridder, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; on the staff of the Beauregard Memorial Baptist Hospital; died Sept. 6, aged 72, of heart failure.

Seiffert, Isadore ⊕ Forest Hills, N. Y.; Eclectic Medical College of the City of New York, 1906; served on the staff of the Bronx Hospital in New York City; died Aug. 19, aged 68, of carcinoma of the pylorus.

Silverman, Max Kaufman ⊕ Long Beach, N. Y.; Baltimore Medical College, 1913; affiliated with Long Beach Memorial Hospital, where he died July 4, aged 63, of myocardial infarction.

Sodaro, Anthony ⊕ Chicago; Loyola University School of Medicine, Chicago, 1916; affiliated with St. Anne's Hospital, Mother Cabrini Hospital, and the Oak Park (Ill.) Hospital, where he died Sept. 24, aged 69, of coronary thrombosis.

Stanbery, Henry, Cincinnati; Miami Medical College, Cincinnati, 1899; served during World War I; member of the American Academy of Ophthalmology and Otolaryngology; died Sept. 2, aged 80, of cardiovascular disease.

Stokes, Merle Benefiel ⊕ Houston, Texas; Rush Medical College, Chicago, 1909; specialist certified by the American Board of Surgery; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served during World War I; on the consulting staff of Memorial Hospital and on the honorary staff of St. Joseph's Infirmary, where he died Sept. 11, aged 73, of pulmonary embolus.

Stull, Samuel Lewis, Vine Grove, Ky.; University of Louisville (Ky.) Medical Department, 1917; died in Veterans Administration Hospital, Louisville, May 3, aged 67, of cerebral thrombosis and arteriosclerosis.

Taylor, Herbert William ⊕ Haverford, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1919; certified by the National Board of Medical Examiners; for many years physician for the Haverford College; affiliated with Bryn Mawr (Pa.) Hospital; died in Mercy Hospital, Watertown, N. Y., Aug. 17, aged 62, of injuries received in an automobile accident.

Teaford, Schuyler Ferree ⊕ Paoli, Ind.; Hospital College of Medicine, Louisville, 1898; served during World War I; for many years county health officer; died in King's Daughters Hospital, Madison, Aug. 23, aged 80, of cancer of the colon.

Truitt, Berton Cleveland, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1908; died Aug. 21, aged 67, of carcinoma of the lung.

Waffle, Clara Wilhelmena Reames, Astoria, Ore.; University of Oregon Medical School, Portland, 1907; at one time city health officer; affiliated with St. Mary's and Columbia hospitals; died Aug. 31, aged 79, of cerebral hemorrhage.

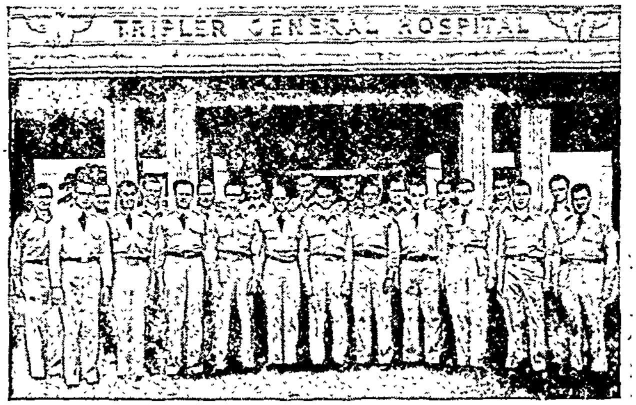
Wells, James K., Sharpsburg, Ky.; Kentucky School of Medicine, Louisville, 1894; died in Owingsville Aug. 14, aged 85, of cerebral hemorrhage.

Zweig, Hedwig ⊕ New York City; Schlesische-Friedrich-Wilhelms Universität Medizinische Fakultät, Breslau, Prussia, 1923; specialist certified by the American Board of Pediatrics; affiliated with Beth Israel Hospital, where she died recently, aged 57.

GOVERNMENT SERVICES

ARMY

New Interns at Tripler Army Hospital.—The picture below shows a group of newly arrived interns who have begun their year of training at the Tripler Army General Hospital in Honolulu, Hawaii. The hospital serves the Army, Navy, and Air Force in the Pacific Ocean area. This 13 story hospital, dedicated Sept. 10, 1948, is located on 366 acres of sloping mountainside commanding magnificent views of Pearl Harbor, Waikiki Beach, Diamond Head, and other famous land marks visible from the patients' wards. It has a bed capacity of 1,500 and nine operating rooms. The hospital is designed and constructed to resist lateral forces greater than those produced by the severest earthquakes on record. It was named in honor of Charles Stewart Tripler, a distinguished member of the Army Medical Corps, who among other things was medical director of the Army of the Potomac during the Civil War.



Personal.—Col. Carl Tempel, chief of medical service, Fitzsimons Army Hospital, Denver, and associate clinical professor of medicine, University of Colorado Medical School, on Sept. 15-16 addressed the staff and medical officers in military training at the Medical Field Service School, Fort Sam Houston, Texas, on diagnosis and treatment of tuberculosis. The speech was followed by a panel discussion and case presentations.

OFFICE OF DEFENSE MOBILIZATION

Hospital Personnel Shortage.—Disturbed by the shortage of health manpower, particularly with the critical situation in many hospitals, the Health Resources Advisory Committee of the Office of Defense Mobilization has appointed a subcommittee on hospital services to collect, analyze, and disseminate the available knowledge of this field. The subcommittee is now preparing a handbook on personnel utilization in hospitals, for use by all concerned. The handbook will be made up of series of pamphlets, each dealing with one specific problem, and the first pamphlet will be ready for distribution this fall. As a preliminary step, this committee and the subcommittee on hospital services have analyzed the problem and have made a number of suggestions for its solution. The analysis and suggestions, printed as a small brochure, show the reasons for the personnel shortage, particularly with regard to nurses, and what can be done by civilian hospital governing boards, medical and dental staffs, administrators, and nurse directors to help this situation. The committee then lists 13 steps that have proved successful in many hospitals and suggests that these steps be considered for appropriate action in all hospitals. The chairman of the subcommittee on hospital services is Mr. Oliver G. Pratt, executive director, Rhode Island Hospital, Providence, R. I.

PUBLIC HEALTH SERVICE

Appointments to Mental Health Council.—Surgeon General Scheele has announced that Dr. Maurice Levine, director, department of psychiatry, University of Cincinnati College of Medicine, Dr. Howard P. Rome, consultant in psychiatry, Mayo Clinic, Rochester, Minn., and Mrs. Ruth Hamblen Morrison, Portland, Maine, have been appointed to serve on the National Advisory Mental Health Council. Mrs. Morrison, wife of Dr. Alvin Alward Morrison, of Portland, has long been an active participant in such community organizations as the Red Cross, School Commission, Parent Teachers' Association, and Child and Family Welfare Board. She is past president of a number of Portland women's clubs. The council's 12 members are appointed for a period of four years. In addition, there are two ex officio members representing the Veterans Administration and the Armed Forces Medical Policy Council, and liaison representatives of the Surgeon Generals of the Air Force, the Army, and the Navy.

Award to Enzyme Chemist.—Surgeon General Scheele has announced that the American Chemical Society has elected Alton Meister, M.D., 31, of the National Cancer Institute, to receive the 1954 Paul-Lewis Laboratories award in enzyme chemistry. The Paul-Lewis award, consisting of a gold medal and $1,000, is given each year to the outstanding American enzyme chemist under the age of 40.

Dr. Meister won the award for discovering (1) the mechanisms by which normal tissues and cancer tissues cause the exchange of chemical groups between amino acids and the breakdown products of sugar and, (2) that vitamin B_6 is necessary for this exchange. Glutamine, an important compound present in almost all tissues, was found to be the key substance in many of these reactions. Also, in the course of these experiments, a number of new compounds called keto acids were isolated in crystalline form for the first time, and the way the body converts them to amino acids was determined. These fundamental studies may be helpful in explaining the growth processes of cancer cells.

Dr. Meister, senior surgeon in the Public Health Service commissioned corps, joined the National Cancer Institute in 1946. Since 1951 he has been head of the clinical biochemical research section of the laboratory of biochemistry. A native of New York City, he received his bachelor of science degree from Harvard University in 1942, and his degree of doctor of medicine from Cornell University in 1945.

Personal.— Dr. Maurice C. Pincoffs of Baltimore, professor of medicine in the University of Maryland School of Medicine since 1922, has been appointed to serve on the National Advisory Arthritis and Metabolic Diseases Council of the Public Health Service. Dr. Pincoffs, recent president of the American College of Physicians, has for many years been editor of the *Annals of Internal Medicine.* He is president of the Medical and Chirurgical Faculty of Maryland, regent of the American College of Physicians, and councilor and ex-president of the American Clinical and Climatological Association.

VETERANS ADMINISTRATION

Twenty Million Veterans in Civilian Life.—The statistical summary of its activities released by the Veterans Administration, Washington, D. C., Aug. 31, shows that as of that date there were in civilian life 20,219,000 veterans, a preliminary figure subject to revision. Of that number the average daily patient load in VA and non-VA hospitals was 105,543. The average daily member load in VA domiciliaries was 16,808. The total of new VA hospitals completed was then 54, 12 hospitals were still under construction, and there had been 50 additions to, and conversions of, hospitals.

FOREIGN LETTERS

BELGIUM

History of Medicine.—For a long time a movement has been under way to organize in Belgium courses in the history of medicine. The Belgian Committee for the History of Sciences has just emphasized again the importance of the history of medicine, not only for general culture but also for the education of the future physician. In addition, it recalls the place occupied by this discipline in higher education, both in Europe—especially in Switzerland, Italy, France, and Germany—and in America and even Asia; the creation throughout the world, Belgium included, of museums of medical history; the regular scientific activity of national associations, groups, and committees, which are becoming more numerous; the existence, in numerous countries, of specialized periodicals assuring publication of works by medical historians; the uninterrupted success of the International Congresses of the History of Medicine, started in Belgium in 1920, which have already brought together, on 13 occasions, specialists from most of the nations. The committee requested the authorities to include this course of instruction in the program of the doctorate, that is, in the sixth year of study.

Campaign for Good Milk.—A national campaign has been organized by the Belgian Red Cross with the support of the Ministry of Agriculture and leaders of the dairy industry to promote the consumption of good milk. The problem is to convince the public in Belgium, as in the Nordic and Anglo-Saxon countries, of the nutritive value of milk. Much progress is yet to be made in the field of general hygiene, although notable improvements have been brought about since 1947.

The campaign, which has been in operation throughout 1953, was designed to turn the attention of the population to the value of milk and milk products and thus to increase their consumption. A new attitude must be created in the population and at the same time new habits must be established in relation to the use of milk. Although the crusade is addressed primarily to the consumers, it is divided into two sections: (1) action addressed to the consumer (adults and young persons) and (2) action to be taken among producers and dairies.

Psychiatry in the Congo.—In a well-documented memoir just published by the Belgian Royal Colonial Institute, Baudoux approaches the vast problem of psychoses among the Negroes of the Congo from the medical and the administrative points of view. He believes that mental disease is rarer than among Europeans and that the frequency is greater among the "civilized" natives and males. He lists the following conditions as occurring in the Congo: (1) schizophrenia, of the classic type; (2) paranoia of the mystical type (religious influence) or megalomaniac (overcompensation); (3) anxiety psychoses, frequently in connection with natural perils (wild beasts) or supernatural dangers, with the author pointing out that leopards and sorcerers still exist in the Congo, while in Europe wolves and sorcerers have disappeared; (4) cyclothymia, which some African observers believe to be rare, including cases—always cited, but without much precision—in which natives let themselves die under the influence of a spell, which may be attributed to melancholia; (5) infectious psychoses due to trypanosomiasis, general paralysis, and occasionally meningovascular syphilis; (6) epilepsy, which is frequent and severe; (7) oligophrenia, seen in its various stages, and cretinism that may be due to goiter; (8) arteriosclerotic and senile dementia, rarely; (9) neuroses seen include hysteria and sexual impotency; (10) psychoses due to cannibalism and alcoholism, rare at present; and (11) attacks of psychomotor agitation of the Amok type (epilepsy and acute delirium). Psychoses associated with pellagra are not seen, although pellagra is common.

Cutaneous and Venereal Diseases in the Belgian Congo.—Lapiere presented to the Royal Academy of Medicine of Belgium the results of a broad inquiry into cutaneous and venereal diseases in the Belgian Congo. Among members of the white race, skin diseases are no more frequent than they are in temperate climates; the majority of the dermatoses noted among them are similar to those seen in our offices. Leprosy and yaws are almost nonexistent among the white colonists, owing to the hygiene of the white man. Precautions do not always protect white men from dermatoses caused by insect bites. Europeans, consequently, suffer frequently from filariasis.

The study of scabies led to the following conclusions: Scabies develops chronically among the natives. Each person becomes immunized gradually to the acarus. Among infected populations numerous persons have no clinical evidences of the disease but carry the infection.

The author reports the opinion of a number of physicians in the brush, according to whom leprosy (Hansen's disease) is, in certain districts, increasing rather than diminishing. Leprosy does not seem to be very contagious; the nursing and medical personnel of the great leprosariums rarely contract the disease. The proportion of persons with leprosy is lower among the riparian population, who bathe regularly. Like scabies and pyodermia, this condition is favored by a lack of hygiene and by promiscuity. Scabies provides a gateway for yaws. A single injection of 2,400,000 units of penicillin seems to be the treatment of choice.

The incidence of venereal diseases is increasing generally on an ascending curve, especially among the natives. The commonest is gonorrhea, which is twice or three times as frequent as syphilis. Cases of venereal lymphogranuloma (Nicolas-Favre) disease may be found; the soft chancre is much rarer. The epidemic index of syphilis among the white persons in the colony is higher than that which was reached at the time of the recent war and postwar epidemics.

The author suggests the following social measures for control of venereal diseases: 1. Declaration of all venereal disease to a competent medical service should be compulsory, under pain of prosecution. 2. In each case of recent infection, attempts should be made to reach the source. 3. Periodic examinations of prostitutes should be carried out. 4. Lectures should be given periodically to the Europeans and the "civilized" natives.

BRAZIL

Diagnosis of Schistosomiasis.—Prof. Samuel Pessoa, of the University of São Paulo, has published in the *Brasil Médico* the results of his researches on diagnosis of schistosomiasis Mansoni on the basis of laboratory tests. Professor Pessoa differs in his opinion from Gelfand, who holds that the Formol-gel test and the intracutaneous reaction have the same diagnostic value. In his opinion the intracutaneous reaction always proves superior because in his experience a positive reaction is obtained in 87.5% of children who have schistosomiasis and in 96.8% of adults. In 90 cases of schistosomiasis in which Professor Pessoa used the Formol-gel test, he obtained positive results in 23.3%. In cases in which only the intestinal symptoms were prominent, the reaction was positive in 14.2%, whereas in cases with hepatomegaly it was positive in 26.1%. In cases of enlargement of the liver as well as of the spleen, the incidence of positive reactions ranged from 28.5% in cases of compensated cirrhosis up to 46.1% in cases of decompensated cirrhosis.

Volvulus of Megacolon.—Before the Regional Medical Congress of the Associação Paulista de Medicina, held in Ribeirão Preto, Drs. Arrigo Raia and Oswaldo Mesa Campos reported that from 1936 to 1952 they had observed 47 patients with

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

acute intestinal obstruction among 148 with megacolon at the first surgical clinic of the medical school of the University of São Paulo. Nine of these patients had obstruction due to stercoroma and 38 due to volvulus of the sigmoid. Studying the medical literature, they found that this complication of megacolon is not common. In the Nordic literature there are many cases of volvulus of the sigmoid and the authors remember the possibility of megacolon being the cause of volvulus in those countries. The treatment of obstruction due to stercoroma consists of manual extirpation of the lesion with the patient under general anesthesia. Dr. Eurico Branco Ribeiro performs a laparotomy and removes the stercoroma.

Until a recent date there was no standard treatment for volvulus in cases of megacolon. The patients of the present series were operated on by various surgeons who used different techniques, such as simple distortion of the volvulus, distortion of the volvulus and suture of the perforation of the sigmoid, distortion and exteriorization of the sigmoid, distortion and manual extirpation of the stercoroma, distortion and colostomy (of the cecum and the sigmoid colon), distortion and colostomy of the transverse colon, distortion and sigmoidectomy with end-to-end anastomosis, distortion and pelvirectal sphincterectomy, and distortion and pulling through of the abdominoperineal resection of the rectosigmoid.

After studying the results obtained with these various surgical procedures, Drs. Arrigo Raia and Mesa Campos concluded that the best procedure in such cases is distortion of the volvulus and colostomy of the transverse colon; this procedure not only cures the acute complication but also includes the first stage of the final operation for the treatment of megacolon, which is done in three stages in their hands. The first stage consists of colostomy of the transverse colon, the second stage of abdominoperineal resection of the rectosigmoid, and the third stage of closure of the colostomy.

DENMARK

Vital Statistics.—The Danish public health authorities have now published a report by Dr. Karen Dreyer and Dr. Henry Hamtoft on the health of Denmark for 1951 and 1952. The adoption of the new international nomenclature for death certificates has, of course, interfered somewhat with a comparison of the most recent years with earlier years. But this is more than compensated for by the opportunity now presented for comparisons on an international scale. With a population of 4,300,000 in 1952, Denmark had 17.8 live births per 1,000 inhabitants and 9 deaths per 1,000 inhabitants that year. Between 1951 and 1952, there was a rise in the death rate up to the age of 15 years and after the age of 45 years, whereas it showed a fall between these two ages. Certain diseases show a remarkable change in incidence from year to year. Poliomyelitis is a case in point. In 1951 there were only 383 such cases, and only 20 of them were paralytic cases. In 1952 the corresponding figures were 5,676 and 2,450 respectively. In the same two years there was a remarkable change, this time in a more favorable direction, in the incidence of acquired syphilis, with 441 notifications of it in 1951 and only 217 in 1952. On the other hand, the number of notifications of gonorrhea was much the same in the two years, with 7,093 in 1951 and 7,017 in 1952. The number of acute infections of the lungs showed a considerable rise in the same period, and the number of notifications of croupous pneumonia rose from 5,342 in 1951 to 6,100 in 1952.

In the notification of deaths, there are fewer sudden changes from year to year, but even here there are some figures worth attention; for example, the number of deaths from pulmonary tuberculosis fell from 506 in 1951 to 428 in 1952. The number of deaths from other forms of tuberculosis showed a corresponding fall, from 67 to 49. As was to be expected, during the same period there was a rise, but only a moderate rise, in the number of deaths from malignant disease and heart disease, the former from 7,615 in 1951 to 7,772 in 1952. There was actually a fall from 1,664 to 1,116 in the number of deaths from pneumonia. The same report gives useful information on the activities of maternity hospitals and allied institutions for childbearing. At the present time, the mother who is not confined at home spends, on the average, 10 days in the hospital in which she is confined.

LONDON

Drummond Research Fellowship.—In August, 1952, Sir Jack Drummond and his family were brutally murdered in France by an as yet unidentified assailant. To commemorate his memory and his outstanding work in the fields of biochemistry and nutrition, his many friends, colleagues, and former students have decided to institute a memorial to him in the form of a Drummond Research Fellowship in Nutrition, to be tenable in any university or appropriate research institution. A committee representing medicine (Lord Horder), biochemistry (Professors A. C. Chibnall, G. F. Marriam, and F. G. Young), the Medical Research Council (Sir Harold Himsworth), and the Ministry of Food, has launched an appeal for £25,000 for the endowment of such a fellowship. The chairman of the committee is Lord Woolton, who was Minister of Food during World War II when Drummond, as scientific adviser to the ministry, made such a brilliant contribution to the nutritional welfare of the nation. In a letter launching the appeal, Lord Woolton "recalls the great debt that we in Great Britain owe to him for his work as scientific adviser to the Ministry of Food during the war." Indeed, it is probably not going too far to say that it was Drummond's unique combination of outstanding knowledge of nutrition, persuasive tongue, and "crusading zeal" (to use a phrase of Lord Woolton's) that saved Great Britain from starvation. He was almost as well known in the United States, and there was nothing he enjoyed more than a trip to renew his many friendships in the States. Friends who want to contribute to this memorial may send subscriptions to the Drummond Memorial Fund, Westminster Bank Ltd., 154 Harley St., London, W.1.

The Dentists and the National Health Service.—The story of the relationships between the Ministry of Health and the dental profession is even more tragic than that of the relationships between the ministry and the medical profession. In his presidential address to the British Dental Association in July, the president described the present scheme as a failure. He went on, "This failure is in large part due to the ignoring by the Minister of Health of advice from men of ability and high-mindedness, whose concern has always been the welfare of the community and the dental profession, which are wholly interdependent. It would have been possible in 1948 to establish a dental service that would have provided a sound foundation to build on. With goodwill on both sides—and that such things as 'sides' exist in this connexion is the greatest tragedy—it is even now, after five wasted years, not too late to formulate a scheme that will add to the prestige of our profession and be of lasting benefit to the whole population . . . Of course there were a few dental practitioners who were not conscientious and who did not play the game. That happens in every profession. It happens even in the business of politics. In my opinion, one politician alone has done far more harm to the dental profession and the community than all our sinners added together."

Wellcome Centenary Exhibition.—The name Wellcome is such a household name in Britain that it is difficult to realize that the man who made it so familiar, Sir Henry Wellcome, was born in Wisconsin, was a protégé of the father of the Mayo brothers, and received his pharmaceutical training in the United States. The centenary of his birth (Aug. 21, 1953) is being commemorated by a special exhibition at the Wellcome Research Foundation, which was opened by Dr. W. G. Wyckoff, scientific attaché to the American Embassy in the unavoidable absence of the American ambassador. Sir Henry Dale, the chairman of the Wellcome Trust, also took part in the ceremony. The exhibition shows facets and mementoes of all aspects of Wellcome's varied career and interests, from the Sioux rising of 1862 to some of the treasures from his unique collection of ancient medical books and antiques. Also shown are letters from Stanley, the discoverer of David Livingston, and a silver first-aid box supplied to King Edward VII for his motor-car. Full attention is also given to the development of the thriving pharmaceutical business that now straddles the universe, and of the research activities that he inspired, particularly in the Sudan.

Dangers of Marking-Ink.—An interesting series of six cases of poisoning from aniline dye in newborn babies, caused by marking-ink, are reported by J. D. Pickup and Jessie Eeles in *Lancet* (**2**:118 [July 18] 1953). In none of the cases was cyanosis severe enough to require administration of methylene blue, though oxygen was given as a supportive measure in three cases. Three months later, all six babies were well, and none of them had had bronchopneumonia. In all six cases, freshly stamped napkins had been used before they had been laundered. According to the makers, the marking-ink contained aniline, toluidine, copper chloride, sodium chlorate, sodium bisulfate, and hydrochloric acid. The authors comment as follows on the incident: "This incident shows once more the importance of boiling before use all clothing or bedding newly marked with aniline ink. None of the nurses concerned were aware of the potential dangers of their actions. The makers' warning on the bottle had become obliterated by ink running down the sides of the bottle. Everyone who has charge of infants should be warned of the dangers of absorption of aniline from marking-ink. It is advisable that hospital laundry units display a notice stating the importance of fixing the marking-ink by thorough boiling of clothing or bedding."

Blood Transfusion Accidents.—In a long statement on blood transfusion accidents (*Brit. Med. J.* **2**:390 [Aug. 15] 1953), the Consulting Pathologists Group Committee deplores the fact that "a large newspaper-reading public should be introduced to the subject of blood transfusion by headlines that high-light almost every fatality." Although it is admitted that the true incidence of deaths resulting from accidents is not known, the dogmatic statement is made that "the incidence of such fatal cases is grossly exaggerated and needless alarm thus spread." One "large hospital in the London area" is quoted as having had only "in the order of one death in a period of six years, in which 13,000 bottles were transfused."

The statement then deals with "the element of risk" and how to overcome it. "Every step must be taken to minimize the chance of causing death in the attempt to save life. Thus, since the risk has been stated as similar to that of uncomplicated appendectomy, similar consideration should be given to, and plans made for, a blood transfusion as would be given to the question of opening an abdomen for appendicectomy." The fact that the demand for blood always tends to exceed the supply is taken to suggest that "there may be a certain measure of over-prescribing, which adds to the risks undergone by some patients and acts to the detriment of others who are really ill and require a life-saving transfusion." It is considered unjustifiable to place any patient at risk for a pint of blood; such patients would do well with a plasma substitute. "In healthy young women with slight loss of blood from abortion, miscarriage, or at term the natural recuperative powers must neither be forgotten nor superseded."

The blood bank at each hospital should be under the care of the hospital pathologist whose responsibility it is to ensure that "(1) the grouping of the patient and the matching of blood are done only by experienced technicians, resident pathologists, and/or housemen who have been and are thoroughly experienced in the methods, and (2) satisfactory arrangements have been made for the care of the bank and grouping and matching at night and at weekends." There are two essentials for maximum safety in grouping and matching—adequate time in which to do all the tests and the full relevant history of the patient. The procedure for the grouping and matching of blood is now so complicated that up to four hours may be required to allow full time for the interaction of cells and serums in ABO and Rhesus-grouping and in compatibility testing. "Thus two hours is the time of incubation (in tubes to avoid evaporation of the small quantities used); only by this means can A-group readings, Rh-grouping (anti-D), and the possible presence of immune iso-antibodies be clearly determined." Equally necessary is considered to be "the matching of recipient's serum with donor cells suspended in saline at room temperature and, in parallel, suspended in 20% bovine albumin at 37° C. for a minimum of two hours and read microscopically." Also essential is the making and staining of blood film when a sample for matching is taken from the bottle: "this permits detection of the rare instance of massive contamination with bacteria that flourish at 4° C. without causing visible changes in the blood." "These methods," it is stated, "are probably not yet fully adopted by all pathologists, but they ought to be, for only by using them can it be said that every possible precaution against mis-grouping and mis-matching has been taken." In emergency, with suitable proved high titer grouping serums, similar procedures can be used and the times cut to 15 minutes for each test, but "it must be clearly understood that while there is fair accuracy with the shorter method, there still is risk of error."

In giving a transfusion, the matched blood should be handled as little as possible and used with the minimum of delay. The method in use in hospitals in the northeast metropolitan hospital region is recommended. Each bottle of matched blood has a colored (according to the group) tie-on luggage label that bears the donor's bottle number and/or name, recipient's full name and ward, the date of matching, and the signatures of the persons who matched and checked the blood. A centrally situated refrigerator or cold room (controlled at 4 to 6 C) is provided for such matched blood because ward refrigerators are too unreliable and the blood may be frozen or forgotten. The central, matched blood refrigerator should have a record of the blood it contains in a book or on a sheet, giving as a one line entry the patient's (recipient's) name and ward and the donor's name and/or bottle number. Each bottle removed should be signed for and the time and date of removal entered. "Blood should only be removed immediately before use, and only by a member of the medical staff, preferably by the houseman or anesthetist who is to set up the transfusion. Neither the removal of blood from the refrigerator nor the administration (including the follow-on of bottles) should be allowed to be a duty of the nursing staff." The details on the luggage label tied to the bottle should be checked with the bottle number and also with the donor's name and/or bottle number and the recipient's name and ward, (*a*) in the refrigerator-register entry at the time of removal and (*b*) in the ward or theater, with a nurse or other person as witness before the blood is given. The physician should ensure that the person named on the luggage label is the same as the person about to receive the blood.

In grave emergency, when compatibility tests cannot be done, unmatched blood reserved in the central refrigerator for emergency use in the theater, in the maternity wards, or by the maternity flying squad should be used—group O Rhesus-negative blood for women and men who have had a transfusion and group O Rhesus-positive blood for men who have not had a transfusion. Even in such cases, however, it is essential to obtain a sample of the patient's blood before transfusion, so that the patient's own group can be determined later and the patient's serum used for further matching.

NORWAY

Tests for Syphilis in Pregnant Women.—In January, 1948, the head of the Norwegian Public Health Service addressed a circular letter to all physicians, hospitals, and midwives in Norway ordering that samples of blood be taken from every pregnant woman with a view to a serologic examination for syphilis. This step was taken because of the new wave of syphilis connected with the occupation of Norway by the Germans from 1940 to 1945. It will be recalled that during World War I there was a considerable rise in the frequency of syphilis in Norway. Between the two world wars there was a marked fall in the syphilis rate, and the disease became so rare that it was little more than a medical curiosity.

At the serodiagnostic department of the State Institute for National Health, which is under the charge of Dr. Otto Hartmann, the serologic testing of the serum of pregnant women has been undertaken on so great a scale that between May, 1948, and April, 1953, as many as 176,702 pregnant women were tested for syphilis—a number corresponding to more than half the number of confinements recorded in the whole of Norway in the same period. Reporting on this work, Dr.

Else Vogt and Dr. Rønnaug Grelland point out that all the samples submitted for examination were tested by the three following reactions: (1) the Bordet-Wassermann reaction (since January, 1950, with standardized cardiolipin-antigen), (2) the Meinicke Klärung reaction, and (3) the Wadsworth and Brown reaction. The tables reproduced in *Tidsskrift for Den Norske Lägeforening* for Aug. 15, 1953, give the number of seropositive women year by year and the percentage of positive cases. Throughout the five year period under review, 1,371 of the women thus tested gave positive reactions, a mean rate of 0.78% for the whole period. The highest syphilis rate was 1.23% in the first year. During the remaining four years, there was no statistically significant fall in the syphilis rate, which in the last year was 0.78%. A classification of the seropositive women in 10 age groups of four years each, showed that the syphilis rate remained remarkably constant between the ages of 18 and 45. This constancy does not coincide with the well-known observation that the syphilis rate usually rises with age. That it did not do so in the present instance was perhaps because, during the German occupation of Norway, the younger women were particularly prone to contracting syphilis.

Anticoagulant Treatments Compared.—At the medical department (chief, Dr. O. Römcke) of the Drammen City Hospital, considerable advances have been made in the treatment of thromboses and emboli by anticoagulants. To begin with bishydroxycoumarin (Dicumarol) treatment was controlled by Quick's method, and many difficulties were encountered, with up to about 30% mishaps (intoxications) when treatment was given under ambulatory or outpatient conditions. Since the spring of 1951, Owren's method with prothrombin control (proconvertin-prothrombin control) has been adopted. At the same time, the dosage and supervision of the patients were confined to one physician with the result that the mishap rate was considerably reduced. Yet, among 47 outpatients with a total treatment time of about 18 years, there were nine instances of intoxication of which one was alarming. Since August, 1952, bishydroxycoumarin has been replaced by PID (2-phenyl-1,3-indanedione).

Reporting on two series of cases in *Farmakoterapi* (no. 2, 1953) Dr. A. J. Hellum describes one series treated with bishydroxycoumarin (Dicumarol) and another with PID and argues that the latter represents a definite advance over the former drug. The bishydroxycoumarin series consisted of 33 persons in the hospital cases; 22 had infarcts of the heart, 5 had angina pectoris, 5 had phlebitis and thrombosis, and 1 had an embolism. The total treatment time was 960 days. In the group treated with PID there were 29 patients; 14 had infarcts of the heart, 3 had angina pectoris, 9 had phlebitis and thrombosis, and 3 had an embolism. The total treatment time was 714 days. The initial dose of bishydroxycoumarin was usually 200 mg. on two successive days, and thereafter the dosage was established for each patient. The initial dose of PID was usually 150 mg. on two successive days, and thereafter the dosage for each patient was determined. PID was found to act more promptly, and its effects subsided sooner than those of bishydroxycoumarin. Prothrombin levels within a toxic range were of comparatively short duration. In other words, the number of days during which prothrombin levels were within the toxic range were comparatively few. For these reasons the author concludes that PID possesses several advantages over bishydroxycoumarin, particularly with regard to the more rapid action, more prompt response to corrections of dosage, and the comparatively level prothrombin figures achieved with PID.

Artificial Insemination.—The lay as well as the medical press in Norway, has, of late, had much to say about artificial insemination. Professor Lövset, a gynecologist, is an active advocate of artificial insemination, including heterologous insemination with an unknown man as donor. Some of his arguments are based on the success with which artificial insemination has been carried out in mammals other than man. Prof. Alfred Sundal, a pediatrician, is openly hostile to heterologous insemination, and one of his arguments is that we have yet no guarantee that the technique of this process entails no risk of damage to the ovum or sperm. He points out that, even under normal conditions of conception, some 7% of all the children born to their parents present more or less distressing anomalies that are a source of worry to the parents. Professor Sundal believes that such worry may be increased for the parents who have assumed the responsibility of heterologous insemination.

In January, 1950, a committee was appointed to investigate the feasibility of legislation with reference to artificial insemination. In March, 1953, this committee issued a report in which three of its five members recommended legislative measures. The other two members were against such legislation. The three in favor of legislation have sketched the outline of a law referable to heterologous insemination for married women. According to this outline, such insemination can be undertaken only by physicians especially qualified for it. The husband must give his written consent, and both he and his wife must have reached the age of 25. There must be no risk of the child in question or its progeny suffering from severe mental or bodily disease. Both parents must be in a position to rear the child successfully, and the donor must consent to being kept in ignorance about the recipients of his semen. Similarly, husband and wife must not know who the donor is, and he must not be blood relation of the wife. The progeny of such insemination must have the same legal rights possessed by other children born in wedlock, and the donor is to be under no obligation to either the child or its mother. The physician in the case must be bound by professional secrecy, though he may be called on to give evidence from a legal point of view provided that the identity of the persons concerned is kept secret.

PARIS

International Congress on Arterial Thrombosis.—The International Congress on Arterial Thrombosis was held at Royat last June 6-8 with Professor Laubry serving as honorary president. It was presided over by Professor Leriche, the vice-presidents being Professors Donzelot and Giraud. A large number of French and foreign delegates attended.

Anticoagulants in Coronary Thrombosis.—R. Froment, A. Gonin, P. Cahen, Melle. Ithier, and M. F. Gauthier reported on use of anticoagulants in coronary thrombosis. They said that many physicians are not aware of the undeniable decrease in the mortality in myocardial infarction treated with anticoagulants. The combined results of 11 different statistical reports of a total of 1,361 cases of infarction treated without anticoagulants gave a mortality of 28.7%; in a total of 1,302 cases in which anticoagulants were used the mortality was 13.3%. Conversely, they stressed a drawback to this treatment, an incidence of 20% of hemorrhages in a total of 1,500 patients. The personal experience of the authors leads them to recommend bishydroxycoumarin (Dicumarol), ethyl biscoumacetate (Tromexan ethyl acetate) combined with phenylindanedione. The authors compared a group of private patients and a group of ward patients.

The ward patients consisted of 120 patients with coronary thrombosis. In the 78 patients with the full pattern of myocardial infarction, 14 deaths were noted. The authors stressed that the mortality rate (18%) was not much decreased, but that on the other hand no coronary thromboembolic accident was noted in life and autopsy revealed no important pulmonary thromboses and only one intraventricular thrombosis. No deaths occurred in 36 cases of clinical coronary thrombosis associated with myocardial ischemia. There were five instances of hematuria without overt complications and four of hematuria that necessitated discontinuation of the treatment. To control the use of anticoagulants the authors used determination of the prothrombin time (Quick) alone in the first stage and combined with the heparin test in vitro (according to T. P. Soulier's method) in the second stage. The latter test permits determination of the dose that induces hypoprothrombinemia and maintains the desired hypocoagulability.

There were typical disparities between the prothrombin time and the heparin tolerance test, especially during the first days of treatment.

In the series of 69 cases in patients treated in private practice with bishydroxycoumarin or its derivatives for six months to four years, there were four deaths among 37 patients with typical coronary thrombosis, 5 cases of recurrent coronary disease in spite of treatment for more than two years, and 1 case of cerebral arterial thrombosis. In the 32 cases of angina pectoris without thrombosis two deaths occurred.

Artificial Hibernation and Acute Coronary Thrombosis.—Professors C. Lian, J. Cahn, J. M. Mellon and Miss M. Dubrasquet reported experimental investigations and clinical prospects of use of artificial hibernation in coronary thrombosis. They studied the effect of hibernation on the organism according to Laborit and Huguenard's technique (see The Journal, May 16, 1953, page 262). They were able to note the fall of temperature, reduction of basal metabolism, reduction of the requirements of oxygen, reduction of the heart rate, slight hypotension, and a fall of intracardiac pressure proportional to the body temperature. All these modifications are reversible on warming. The authors stressed that coronary ligature with the patient under ordinary anesthesia provokes death on the operation table or immediately postoperatively in most cases. On the contrary, a coronary ligature performed with the patient under hibernation does not provoke immediate death, except in cases of cardiac wounds, and the patient may survive for many months. According to the authors, these experiments show that artificial hibernation ought to be used with other methods for the treatment of myocardial infarction, as it has an antishock, analgesic, and hypnotic action. It diminishes cardiac excitability and can stop ventricular paroxysmal tachycardia or even prevent it. Moreover, with hibernation the circulatory needs of the organism are restricted, which attenuates the consequences of poor coronary circulation. In addition the "lytic cocktail" used for hibernation has anticoagulant action.

Arterial Thrombosis of the Extremities.—J. Terrasse and R. Cuvelier, in their report on treatment of thrombotic conditions with warm mineral waters, stressed that crenotherapy is really only effective in senile atheromatous thromboarteritis.

Professors M. Mouquin, H. Reboul, P. Laubry, and L. Vercoz reported on serial arteriophlebography and aortography in thromboarteritis of the extremities. The authors reviewed the history of this method, which was begun with intra-arterial injection of the contrast medium by Berberich and S. Hirsch in 1923, the discovery, in 1927 by Egas Nomiz of arterial encephalography, and by the distinction of arterial, tissular, and venous phases. In 1929 R. Dos Santos, A. Lima, and P. Caldas discovered arteriography of limbs and abdominal aorta. The technique was perfected over the next 22 years by Professors Ch. Laubry and Louis Bazy and later in the service of Professor Mouquin and P. Thoyer Rozat at the La Pitié hospital, particularly by use as contrast mediums of the most opaque and most soluble organic iodized compounds. There is a close relation between the rapidity of opacification and tissular lesions. With this new method it becomes possible to study the rapidity of opacification of each arterial segment in any tissular plaque by arteriophlebography.

Oxygenation of Hemoglobin.—Prof. J. André Thomas' original work on the artificial heart and lung has been previously reported on in The Journal. While he was trying to improve this apparatus, it appeared to Thomas that the oxygenation of hemoglobin is due not only to a purely physical phenomenon of diffusion but also to chemical factors. After a series of experiments the author succeeded in extracting this chemical substance, which he named "globine-oxydase." He found it in the aortic blood of a cow, but it was not present in the vena cava nor in the systemic circulation. He extracted this substance from the animal's lung. The active principle is probably an enzyme and its composition resembles that of the already known succinodehydrogenase. The extract is inactivated by potassium cyanide and its activity is not due to the presence of SH radicals; the presence of copper is revealed by the spectrogram. In vitro, when added to the jugular blood of the horse, this enzyme increases oxygen saturation. According to the author, the enzyme acts as catalyser in the fixation of oxygen on hemoglobin by modifying the structure of hemoglobin. It degenerates progressively as it is used, and in its absence hemoglobin is incapable of fixing oxygen. Investigations made on the dog showed that, when injected in a dose of 5 cc., the undiluted extract provoked no shock, no intoxication, and no changes either in the arterial pressure, respiration or temperature; the electrocardiogram remained normal. When the undiluted extract is injected quickly into a dog rendered progressively anoxemic (80%), the oxymetric curve rises up to 90% but the animal dies within a few minutes. Conversely, if 2 cc. of extract, diluted in Ringer's solution are injected in 2 minutes, oxymetric curves rise from 85 to 96% within 2 minutes; they then fall in 13 minutes to 82% (inactivation of enzyme) and with repetition of the injection rise again to 97%. If the diluted extract is injected by drip, curves rise from 85 to 97%. The oxygenation effect lasts for 32 to 50 minutes but subsides after discontinuation of the drip. This experiment completely disproves the previous conception of purely physical fixation of oxygen. Professor Thomas and Mrs. Alfsen Blanc stated in their report on Jan. 26, 1953, to the Academy of Sciences, "It is logical to consider for the future a medical and surgical therapy consisting in the simple injection of such an extract."

TURKEY

Subacute Suppurative Inguinal Lymphomatosis.—In *Klinik* (vol. 10, no. 5), Prof. Halil Gürün, chief of the Kabul Afghanistan Medical School department of dermatology and venereal diseases, reports that, since syphilitic and gonorrheal diseases abound in that country, soft chancres and lymphogranuloma undoubtedly exist. The opportunity to diagnose a case of suppurative inguinal lymphomatosis, however, occurred only at the end of three years. According to the patient, a 32-year-old peasant, the disease began three and a half years earlier, with pustules on the genitals, swelling of the groins, and swelling of the nodules, which developed into open sores. Within two years the condition spread to the anus. Home remedies had been tried. Examination of the patient revealed swollen hard lymph nodes varying from the size of almonds to the size of eggs, and periadenitis in the Scarpa's triangle. Some of the nodes had fistulas, and some had scars. There were recently suppurated nodules, and there was lymphangitis in the surrounding area, with no pain on palpitation or pressure. The skin of the surrounding area was dark dermoepidermitis, and there were vesicular erythematous plaques in the perianal area. The narrowed rectum revealed painful fissures and infiltrated rough surroundings. The patient refused examination by rectoscope.

The venereal disease routine laboratory, Kahn, Meinike, and Wassermann tests were negative. The Frei test gave a highly positive reaction. Blood examination revealed 3,800,00 eryrocytes per cubic millimeter, 8,400 leukocytes, 78% hemoglobin, and 4% eosinophils. The sedimentation rate was 9 mm. after one hour and 13 mm. after two hours. The histological diagnosis made by Professor Broussy of the Kabul Medical School was venereal lymphogranuloma (Nicolas-Favre-Durand disease) of the inguinofemoral nodes.

The patient was given one 250 mg. capsule of chlortetracycline (aureomycin) six times daily for one week, one capsul four times daily during the second week, and one capsul three times daily during the third and fourth weeks. The man was given a total of 45 gm. of chlortetracycline. The inguinofemoral nodes and the perianal manifestations completely subsided, and there was considerable amelioration at the anus and the narrowed rectum. Prior to the diagnosis, the patient was given 8 million units of penicillin and sulfonamides for 10 days, without any beneficial effects. As there were no more antibiotics available, the patient was discharged. Questioning revealed that other such cases exist in his village, which, because of the absence of roads, is difficult to reach.

MEDICAL MOTION PICTURES

Surgical Treatment for Congenital Pulmonary Valvular Stenosis: 16 mm., color, sound, showing time 19 minutes. Prepared by George H. Humphreys, M.D., Columbia-Presbyterian Medical Center, New York. Produced in 1951 by, and procurable on rental or purchase from, Sturgis-Grant Productions, Inc., 314 East 46th Street, New York 17.

After a brief description, with diagrams, of the anatomy and physiology of the condition, a 7-year-old child is shown who exhibits typical signs and symptoms of pulmonary stenosis. Heart sounds are recorded on the sound track, and the roentgenogram and electrocardiogram are shown, as well as cardiac catheterization tracings. The main steps in the procedure of pulmonary valvulotomy are demonstrated, with emphasis on the special instruments employed in the operation. The patient's improvement is shown, and comparative postoperative findings are discussed. The film illustrates a highly specialized surgical procedure and it will be of value to vascular surgeons. It will also be of interest to cardiologists, pediatricians, and general surgeons as a demonstration of what can be done with cases of this type. The photography is excellent.

Lease on Life: 16 mm., black and white, sound, showing time 23 minutes. Produced in 1945 by Emerson Yorke Studios, New York, in cooperation with the U. S. Public Health Service, Federal Security Agency, Washington, D. C. Procurable on loan from National Tuberculosis Association, 1790 Broadway, New York 19, or state or local tuberculosis associations.

This film opens with the family doctor of the horse and buggy era coming back as a ghost-like apparition to look in on the Jones family. From time to time, his observations of the family's progress in the face of advances in medical science are made known to the viewers. The Jones family consists of four generations, each of whom has certain health interests. The positive aspects of health protection and preventive medicine are illustrated by the well-child clinic attended by the infant, the school health examination, the industrial health program for the wage earner, and clinic attendance by the grandmother. Generally the preventive medicine aspects of the film and the advice on health protection are technically correct. Because all health activities are centered in the clinic, the film will be most applicable to the situation in metropolitan areas. Only passing mention is made of the family physician, and he is ignored so completely that the implication is that the family physician does not figure in preventive medicine, nor in hospital care where a staff physician cares for the victim of a heart attack. This would be an excellent film to use for presenting to adult groups the fundamental principles of preventive medicine, if it did not so completely ignore the family physician as an important factor in the health services of a community. Technically, the film is well done.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Public Health: Compulsory Confinement of Infected Persons.—The petitioner was confined in the Southwest Florida State Sanitarium at Tampa pursuant to a commitment issued by the county judge of Dade County, under the provisions of a 1949 law relating to the compulsory isolation and hospitalization of tuberculous persons. To test the validity of this detention, the petitioner filed habeas corpus proceedings in the Supreme Court of Florida, Division B.

The petitioner claimed that the statute in question was unconstitutional and that his confinement thereunder was unlawful. Recent history of public health matters, said the Supreme Court, shows that tuberculosis is recognized as one of the most dreadful diseases and one of the greatest killers. The State spent millions of dollars prior to 1949 in an attempt to minimize as far as possible the spread of this terrible disease. It established a few hospitals and clinics and carried on a program of detection, education, and advice. It recognized that those afflicted with this disease were a menace to society. They walked the streets; went to public places such as theaters, hotels, and restaurants; and rode in common carriers. In their homes and other places they came in close contact with relatives and friends and the general public. They not only suffered themselves but left disease, misery, sorrow, and death in their wake. Prior to 1949 the Legislature had not enacted any law for compulsory confinement or quarantine with reference to persons afflicted with this disease. The real reason, the court continued, why no such law had been passed prior to that time was because there were not sufficient hospitals or sanitariums provided by the state to properly take care of these people and it would have been useless to enact a law for compulsory confinement or quarantine without the state providing adequate facilities to carry into effect such a law. Although the need had been recognized for many years, the Legislature was confronted with the conflicting demands to provide adequate facilities in the promotion of public health and the general welfare on the one hand and the clamor not to increase but to reduce taxes on the other hand. In 1949, it was recognized that the Legislature would probably levy sufficient taxes and appropriate sufficient money to erect suitable sanitariums in which persons with tuberculosis could be confined and treated. The law under question was, therefore, enacted by the Legislature.

In a prior case decided by the Florida Supreme Court, the appellant was confined on orders of the health officer because she had an infectious or contagious disease. The court in a unanimous opinion said "generally speaking, rules and regulations necessary to protect the public health are legislative questions, and appropriate methods intended and calculated to accomplish these ends will not be disturbed by the courts. All reasonable presumptions should be indulged in favor of the validity of the action of the legislature and the duly constituted health authorities. But the constitutional guarantees of personal liberty and private property cannot be unreasonably and arbitrarily invaded. The courts have the right to inquire into any alleged unconstitutional exercise or abuse of the police powers of the legislature, or of the health authorities in the enactment of statutes or regulations, or the abuse or misuse by the Boards of Health or their officers and agents of such authority as may be lawfully vested in them by such statutes or regulations. However, the preservation of the public health is one of the prime duties resting upon the sovereign power of the State. The health of the people has long been recognized as one of the greatest social and economic blessings. The enactment and enforcement of necessary and appropriate health laws and regulations is a legitimate exercise of the police power which is inherent in the State and which it cannot surrender. The Federal government also possesses similar powers with respect to subjects within its jurisdiction. The constitutional guarantees of life, liberty and property, of which a person cannot be deprived without due process of law, do not limit the exercise of the police power of the State to preserve the public health so long as that power is reasonably and fairly exercised and not abused. The legislative authority in this legitimate field of the police power, like as in other fields, is fenced about by constitutional limitations, and cannot properly be exercised beyond such reasonable interferences with the liberty of action of individuals as are really necessary to preserve and protect the public health. . . ."

The petitioner also made a special attack on the law on the ground that it discriminated against all persons other than those of a certain religious faith and belief. Religious freedom, said the Supreme Court, cannot be used as a cloak for any person with a contagious or infectious disease to spread such disease because of his religion. Accordingly the petitioner's petition for a writ of habeas corpus was denied, and the commitment pursuant to court order was sustained. *Moore v. Draper, 57 So. (2d) 648 (Florida, 1952).*

Effect of Oxygen on Pulmonary Circulation in Mitral Stenosis. —McGregor and associates point out that, whereas until recently studies on the circulatory dynamics of the pulmonary circuit have been confined to experimental animals and to normal human subjects, now investigation of cases of mitral stenosis has demonstrated that a sharp rise in pulmonary vascular resistance takes place in this condition as the pulmonary capillary pressure rises and that this rise is at least partially reversible following mitral valvotomy. Lewis and his co-workers regarded the phenomenon teleologically as a means of protecting the pulmonary capillary bed from unduly high pressures. Westcott and his colleagues suggested that it is the result of anoxia secondary to pulmonary congestion and edema. The latter suggestion is supported by the demonstration that anoxia causes a rise in pulmonary artery pressure in both anesthetized cats and unanesthetized normal human subjects. Thirteen patients with mitral valve disease were selected in order to study the effects of the breathing of high concentrations of oxygen on the pulmonary hypertension found in mitral stenosis. Administration of pure oxygen to these 13 subjects with raised pulmonary artery pressure and raised pulmonary resistance produced a fall in pulmonary pressure in all. In 10 there was an additional significant fall in total pulmonary resistance. There was some correlation between the initial pulmonary pressure and the degree of fall in vascular resistance. There was no correlation between initial arterial anoxia and the fall in pulmonary resistance following administration of oxygen. In spite of this it is felt that local anoxia caused by pulmonary congestion and edema may at least play some part in the development of pulmonary hypertension in mitral stenosis.

Beriberi Heart Disease.—Benchimol and Schlesinger present observations on 22 patients with beriberi heart disease whom they observed during a three year period in Rio de Janeiro. The periods of observation varied from a few weeks to several years. All of the 22 patients were men. Whereas thiamine deficiency among the oriental population is due usually to an inadequate diet, most cases of beriberi heart disease in this hemisphere occur as a result of chronic alcoholism. All the patients discussed here were heavy drinkers, and only 50% had a history of an associated dietary deficiency. All, however, appeared well nourished. Edema was the earliest and most frequent clinical manifestation. Variable degrees of dyspnea occurred in 20 patients during the course of cardiac failure, although it appeared as an initial symptom in two. A certain instability of the pulse rate was an interesting feature, particularly a transient bradycardia that usually appeared at the onset of clinical improvement. Blood pressure variations consisted mostly of a transient hypertension during the course of heart failure. Clinical signs of polyneuritis were present in all but two cases and were rarely of clinical significance. The main roentgenologic and electrocardiographic features proved reversible on thiamine treatment. The occasional diagnostic difficulties in distinguishing cardiac beriberi from hypertensive and arteriosclerotic heart disease are pointed out. There were six deaths caused by heart failure. Five cases came to autopsy, and thiamine deficiency was confirmed in all of them. The unfavorable prognosis of beriberi heart disease in certain cases is due to the prolonged duration of thiamine deficiency leading to an irreversible myocardial fibrosis. This emphasizes the importance of early recognition and suitable treatment. Although vitamin B_1 administered parenterally is considered the specific treatment for cardiac beriberi, some patients respond to bed rest, salt-free diet, digitalis, and mercurial diuretics. The beneficial effects of these nonspecific measures should not, therefore, rule out the diagnosis of thiamine deficiency. Certain irreversible types of cardiac beriberi may show only slight improvement or no response at all to thiamine medication.

Basic Considerations of Obesity.—Jolliffe stresses that obesity is invariably caused by a greater intake of calories in food than expenditure of calories as energy. This fact is important, not only in understanding the cause of obesity but in its treatment. All methods of freeing the obese from excess fat are effective only in so far as they aid in producing and maintaining a calorie deficit. Adjuvants to the low caloric diet, whether medicinal, physical, psychological, or educational, are valuable only in so far as they increase the caloric expenditure or aid the patient to control his appetite and to adhere to the prescribed diet. Those adjuvants that do not aid in one of these ways probably lead to more harm than good. The reducing diet should form the basis of dietary reeducation so that the proper eating habits will continue after the desired loss of weight has been attained. For this reason skipping meals, uncommon or "trick" diets, and high fat diets that do not furnish a sound basis for permanent dietary habits are not recommended. The education of the patient in elementary dietetics, that is, the importance of calorie counting, must be emphasized. A number of persons reduce without ever learning food values. This they do by following a rigid menu and never deviating from the prescribed plan. When the desired amount of weight has been lost, it is promptly regained because the reducer has learned nothing of the energy value of foods. To gain freedom from rigid, monotonous menus, in order to reduce and then stay reduced, it is necessary to learn food values in terms of standard portions.

Excisional Therapy of Aortic Aneurysm.—De Bakey and Cooley are of the opinion that the use of the excisional form of therapy is dependent for the most part upon the location and nature of the lesion. Thus, sacciform aneurysms in which the neck is relatively small and the wall of the parent vessel is suitable for suture may be excised with lateral arteriorrhaphy to repair the aortic defect. Such lesions are usually syphilitic in origin and are most frequently encountered in the upper thoracic aorta, particularly about the aortic arch. The preferable exposure for such lesions involving the ascending and transverse portions of the arch consists of a right anterior thoracotomy through the second or third interspace with cephalad extension by median sternotomy or with extension into the left hemithorax by transeverse sternotomy as the situation demands. For lesions involving the descending limb of the aortic arch, a similar thoracotomy approach is used through the left side. Aneurysms in the lower reaches of the aorta tend to be more extensive and to involve a segment of the aorta itself. This is particularly true of those in the abdominal region that are more likely to be arteriosclerotic in origin and fusiform in type. Accordingly, their extirpation usually requires excision of a varying segment of the involved aorta with the aneurysm and bridging of the defect in the aorta by means of an aortic homograft to restore normal circulation. During the performance of this procedure temporary arrest of the circulation in the aorta distal to the origin of the aneurysm is necessary, raising the question of possible ischemic damage to the tissues below the point of occlusion. In the experience of these authors, no significant ischemic manifestations were observed after such occlusion above the renal vessels for a maximum period of 45 minutes and below the renal vessels for a maximum period of 105 minutes. The surgical approach to aneurysms located in the lower thoracic and upper abdominal part of the aorta is best provided by a left thoracotomy through the resected bed of the rib opposite the origin of the aneurysm with extension into the abdomen as a thoracoabdominal approach if necessary. For aneurysms involving the abdominal aorta below the origin of the renal vessels, an abdominal approach, through a midline incision extending from points well above and below the umbilicus, is preferred. The procedure of excision and replacement with aortic homograft has been done in 10 aneurysms involving the lower thoracic and abdominal aorta with one death from progressive uremia and secondary hemorrhage in a 74-year-old woman. The gratifying early results obtained with this method suggest that it is superior to the treatments that employ promotion of thrombosis and fibrotic organization by occlusion of the parent vessel, introduction of foreign material, or fibroplastic agents.

Adrenalectomy and Sympathectomy in Severe Hypertension.—The clinical course is reported of 82 patients with severe hypertension who were followed from 1 to 33 months after varying degrees of adrenal resection, performed with or without sympathectomy. The indications for operation included three features, namely, average diastolic blood pressure of 122 mm. Hg. or more, failure to respond to intensive medical therapy, and evidences of progressive vascular damage. The tentative contraindications included any one of the following: poor renal function, with excretion of less than 20% of phenolsulfonphthalein 15 minutes after intravenous injection, and/or blood urea nitrogen of over 20 mg. per 100 cc.; convalescence from a stroke or coronary occlusion for less than six months; age of 55 years or more; and inability, for any reason, to cooperate in taking adrenal cortical replacement therapy. Of the 82 patients, 54 were subjected to an Adson type of sympathectomy, plus either subtotal or total adrenalectomy. The modified Adson operation included removal of the 12th thoracic and the upper two lumbar sympathetic ganglions, together with interruption of the three splanchnic nerves. In the case of subtotal adrenalectomy, all adrenal tissue was removed except a remnant about 6 mm. in diameter adjacent to the adrenal vein on the left side. These operations were performed through a subdiaphragmatic, retroperitoneal approach in two stages about 10 days apart. Further observations will be required to determine whether the Adson type of sympathectomy, combined with total or subtotal adrenalectomy, is more or less effective than thoracolumbar sympathectomy, or total adrenalectomy without sympathectomy. Follow-up was too short for evaluation of results in 8 patients; 19 showed an excellent response, in 11 the response was fair, in 25 the response was poor, and 19 did not survive. Only one died from uncomplicated adrenal insufficiency. The usual cause of death was a stroke or a coronary occlusion. Those having paroxysmal dyspnea or congestive heart failure showed the most striking improvement after surgical intervention. This appears to be primarily the result of extensive resections of the adrenal cortex. Objective changes observed in the surviving 63 patients were heart size reduced in 25, improvement of the eyeground in 30, and the electrocardiogram less abnormal in 17. During the first month after the operation, including extensive adrenal resection, a liberal amount of cortical replacement therapy was given, including cortisone, sodium chloride, and desoxycorticosterone acetate. Patients were taught to report untoward symptoms promptly to their physicians and to seek medical attention in the event of a respiratory infection or other febrile episode, in order that replacement therapy could be temporarily increased. With these precautions no patient has required readmission to the hospital for the treatment of acute adrenal insufficiency during the past 24 months.

Disease of Liver with Ulcerative Colitis.—Of 32 patients who underwent liver biopsy, 26 were selected because of clinical or laboratory evidence suggestive of hepatic disease, while the remaining 6 who were without signs or symptoms of hepatic dysfunction served as controls. Two of the six patients were demonstrated to have a normal microscopic picture, two had infiltration with fat, and two had pericholangitis. Five patients had normal livers. The livers of nine patients were infiltrated with fat, but in none of these could the specific lesion have been suspected from the clinical or laboratory survey. Seven of the nine patients had abnormal retention of sulfobromophthalein, more than 5%. The result of the thymol turbidity test was negative in all nine patients. It is of interest that in eight of the nine patients only minor microscopic changes were associated with fat infiltration, and in none was cirrhosis an associated condition. It would seem that in patients with chronic ulcerative colitis many conditions and factors, such as malnutrition, lack of lipotropic agents, anemia, and the toxic effects of undetermined bacterial or chemical products, might be present that would contribute to the production of a fatty liver. In five patients the microscopic findings were pericholangitis with stasis of bile in three; diffuse hepatitis was also present in three. In three, a diagnosis of postnecrotic cirrhosis was considered. Most of the patients with paricholangitis with bile stasis, diffuse hepatitis, and cirrhosis had had a reversal of the albumin-globulin ratio and positive results to thymol turbidity, zinc sulfate turbidity, and cephalin-cholesterol flocculation tests. Definite conclusions cannot be drawn concerning the possibility that the disease in these patients might have been viral hepatitis.

Occult Subacute Bacterial Endocarditis.—Hematological abnormalities overshadowed the classic manifestations of subacute bacterial endocarditis in three men, aged 44, 46 and 60 years, respectively, reported on by the authors. The three patients had anemia with a hemoglobin level of 10.8 gm., 5.5 gm., and 10.8 gm. per 100 cc., respectively; anemia of this type has been observed in 150 of 200 patients with subacute bacterial endocarditis recently reviewed by the same authors. One patient presented anemia of the normocytic and normochromic type, the second had pancytopenia that has not been present in any case previously reported, and the third had hypochromic anemia and neutrophils that contained toxic granules. Although the heart was enlarged and a systolic murmur was heard over the entire precordium in the first patient, attention was focused on the unexplained anemia that for months had dominated the clinical picture and proved refractory to treatment. In the absence of fever, cellular elements in the urine and a palpable spleen, the relation of the anemia to the cardiac findings was not recognized. Necropsy revealed subacute bacterial endocarditis of the mitral valve in this and in the second patient in whom pancytopenia was attributed to toxic suppression of bone marrow activity, since leukemic infiltration and the hyperplasia usually associated with hypersplenic states were absent. The rather pronounced splenomegaly in the second patient was consistent with the tentative diagnosis of an abdominal lymphoma. A brief febrile episode was attributed to pneumonitis. On only one occasion was a cardiac murmur heard by one observer, and repeated examinations by several physicians failed to confirm this finding. In the third patient, cardiac murmurs were absent throughout most of the course of the disease. Leukocytosis present on admission was associated with a pulmonary complication that was probably embolic. Subsequent counts revealed a mild leukopenia. When a murmur was heard late in the course of the disease, cultures of the blood were performed and demonstrated streptococci. The discovery of the murmur led to establishment of the diagnosis and institution of antibiotic therapy. The association of a cardiac murmur and an unexplained anemia or of an unexplained fever and anemia should suggest the possibility of bacterial endocarditis.

*Evaluation of Treatment of Duodenal and Gastric Ulcers in Physical Medicine and Rehabilitation Service. J. Ehrlich.—p. 494.

Value of Occupational Therapy in Peptic Ulcer.—At a Veterans Administration Hospital patients are referred to the physical medicine rehabilitation service as soon as a diagnosis of peptic ulcer is established. The rehabilitation treatment is usually given concurrently with medical therapy, which consists of a modified Sippy regimen that was gradually liberalized. Relaxation and deep breathing exercises are given once or twice a day. Localized residual muscular tension is relieved by passive movements of the arms and legs or by moving the whole body. An awareness of the difference between a state of muscular tension and that of relaxation must be developed. Relaxation and deep breathing exercises bring relief of the tension states. The aim of occupational therapy is to divert the interest of the patient from his body through the selection of a proper occupation. Work should be given that will sustain interest. Through the use of a variety of mediums, such as plastics, woodwork, art, stencilling, jewelry, leather working, and weaving, specifically selected to meet the individual needs and inclinations of the patient, the nervous manifestations noted on initial interview of the ulcer patient are gradually alleviated and at times disappear altogether. Patients no longer gaze blankly into space or sit rigid. They have forgotten self in the expressing of creative ideas. The therapist is working toward three goals in treating the tense ulcer patient: first, an externalization of interests, thus diverting the mind of the patient from his illness toward a new interest; second, an increase in his work tolerance, starting slowly and gradually changing the activity to one of greater significance and more purposeful character; and, third, resocialization, by drawing the patient into a group situation. A total of 204 patients with peptic ulcer (183 duodenal and 21 gastric) were referred to the rehabilitation service. Of these, 190 were improved and 14 were unchanged. Patients in the older age groups did not respond as well as the younger patients. The author feels that occupational and corrective therapy are beneficial to peptic ulcer patients.

Anemias Caused by Copper and Iron Deficiency in Dogs.—Van Wyk and his co-workers found that dogs made anemic as a result of iron deficiency had the classic changes in peripheral blood consisting of relatively normal numbers of red blood cells, with a marked decrease in red blood cell size, hemoglobin content, and hemoglobin concentration. In the bone marrow, iron deficiency resulted in hyperplasia of hemoglobin-deficient normoblasts, with no appreciable shift to the left or evidence of a disorder of maturation. This is in line with the generally accepted conclusion that the hemopoietic abnormality of iron deficiency can be explained solely on the basis of a deficiency of hemoglobin. In contrast to the anemia of iron deficiency, the anemia that occurred as a result of copper deficiency was characterized by a reduction in the number of erythrocytes, with the maintenance of relatively normal red blood cell indexes. In the marrow, there was no evidence of a deficiency in hemoglobin content but rather evidence of defective development of cells of the erythrocytic series. Irrespective of any role that copper may play in the metabolism of iron and the formation of hemoglobin, the present observations are suggestive that, at least in the dog, copper is essential for the normal maturation of the erythrocytic elements of the marrow and the production of normal numbers of red blood cells.

*Inguinal Hernia in Men Over 55: Elective Versus Emergency Operation. M. W. Debenham and C. Davis.—p. 403.

Inguinal Hernia in Men Over 55.—Debenham and Davis say that many men over 55 years of age endure the discomfort of an inguinal hernia, because they have been led to fear the complications of surgery and have been given the impression that the chance of the hernia recurring is great. The authors feel that inadequate attention has been given to the dangers that may result if the hernia is not repaired and an emergency operation becomes necessary. In a recent series of 210 cases of intestinal obstruction in patients over 60 years of age, the mortality was 54%, and half of the obstructions were due to strangulating hernia. This raises the question whether it would not be possible to eliminate this type of emergency by elective surgery before the strangulation occurs. A study was made of the results of 365 hernioplasties done at the San Francisco Hospital during a three year period. Of these, 194 patients were men over 55 years of age at the time of operation, and the remainder were patients from 35 to 55, and served as a control group. The main interest was a comparison between those operated on as emergencies because of strangulation and obstruction and those who had an elective operation. The mortality in emergency hernia operations in this series was 10% as compared to less than 0.5% in those in which elective operation was done. The recurrence of hernia was not appreciably greater in elderly patients than in a similar group of young adults. The authors feel, therefore, that unless there is some special reason for not operating, almost all hernias should be repaired regardless of chronologic age.

Action of Human Gastric Juice on Human Blood Clots.—The influence of the gastric juice in favoring or disturbing hemostasis in gastroduodenal hemorrhage has received relatively little study. Clinically, such bleeding may cease for a while but may become active again after some hours, suggesting the possibility of clot disruption by the gastric juice. This study was undertaken to gather quantitative and qualitative data on the interaction of gastric juice and blood clots. A wellretracted whole blood clot, derived from a known volume of blood, was placed in a glass tube containing a known volume of gastric juice. The tube and its contents were then placed in a metal rack, strapped to a mechanical vibrator, and incubated for a given time at 37 C. The clots were weighed before and after they were put in the gastric juice. The weight lost was taken as an index of the amount of clot disruption caused by contact with the gastric juice. A number of normal adults of both sexes were used as donors. All glassware for drawing and collection of the blood was siliconized. Usually 50 ml. of blood was drawn from each subject and carefully transferred to a beaker from which it was then measured out in 1 ml. quantities into 60 by 15 mm. glass tubes, which were corked and placed in the incubator at 37 C for 2 hours. Clot retraction was taken as maximal after that time. The clot lytic activity of normal human gastric juice appeared to be a function of the concentration and pH of the juice and the size and cellular composition of the clot. Where peptic activity is greatly reduced or absent, swelling of the clot and not lysis occurred. Moderate dilution enhances the clot lytic activity of gastric juice, as it does the rate of coagulation of normal blood and plasma. The increased lytic activity of the gastric juice on moderate dilution may be due to reduction of peptic inhibitory factors present in the juice or possibly to an optimum physicochemical readjustment between substrate and enzyme.

Surgical Treatment of Skeletal Metastases.—According to Stein and Beller, secondary skeletal malignant lesions are more frequent than primary malignant bone tumors. The commonest are carcinoma metastases by the lymphatic or blood stream. Occasionally there may be direct extensions of a neighboring soft tissue malignant tumor into bone. In addition, the lymphomas or leukemias may be present with osseous manifestations. Metastases by retrograde lymphatic extension favors bone nearest the primary growth. Thus, mammary carcinoma favors the ribs, the thoracic portion of the spine, and the skull. In prostatic cancer, it is the sacrum, the lumbar portion of the spine, and the pelvis that are most commonly involved. Hematogenous metastatic deposits may occur in any of the bones. They are, however, rarely seen distal to the knees or elbows. There are two principal forms of bone metastases, osteolytic and osteoblastic. Osteoblastic lesions are accompanied by serum alkaline phosphatase elevation. Purely osteolytic lesions produce little or no rise in the alkaline phosphatase level. The greater the degree of bone destruction, the higher may be the serum calcium and phosphorus levels. In osseous metastases accompanied by impending or actual pathological fracture, the usual methods involving the use of plaster of paris supports, splints, and traction are often insufficient and have, moreover, confined patients to bed when the lesion involves the lower extremities. This results in further loss of bone substance from disuse, increased likelihood of renal disturbances, and the problem of bed sores. The authors believe that intramedullary fixation is the treatment of choice for actual or impending pathological fractures of the long bones. The clover leaf nail of Küntscher is used in the femur. In other long bones, especially the humerus, the three point fixation technique of Rush is preferred. When pathological fracture has occurred, the open method of intramedullary nailing is the procedure of choice. The authors present histories of three patients in whom the Küntscher intramedullary clover leaf nail was used in pathological fractures of the femur. A rare case of Hodgkin's disease, originating as destructive spondylitis of the lumbar spine, is reported. Temporary clinical relief of back pain was obtained by a spine fusion operation. The subsequent lymphagenous dissemination was temporarily controlled by high voltage roentgen therapy and the use of nitrogen mustard.

Isoniazid in Treatment of Leprosy.—Latapi and co-workers treated 14 patients with leprosy ranging in age from 14 to 62 years. Tablets of isoniazid (Nydrazid) were given in doses that varied between 3 and 5 mg. per kilogram of body weight per day. No other therapy was used except when it was necessary to treat intercurrent disease, for which penicillin was given parenterally or other drugs were given that have been proved not to have any effect in leprosy. Thirteen of the 14 patients had the lepromatous type (one diffuse and 12 nodular) of the disease, and one patient had tuberculoid leprosy. Clinical and histopathological changes indicated that isoniazid was therapeutically active in the lepromatous type of leprosy. Benign or moderate lepra reactions occurred in about half of the patients with the lepromatous type treated. The results obtained justify continuation of this study. The drug was well tolerated, and no toxic manifestations could be detected.

Passive Immunization in Poliomyelitis.—Siegel and Greenberg studied the epidemiology of multiple household infections occurring in New York City from 1949 to 1952 to answer questions regarding the chances of clinical infection after household exposure, the role of passive immunization in the community control program, and the guide lines for the distribution and application of gamma globulin. They found that the percentage of households affected with more than one case of poliomyelitis in a given year varied with the annual incidence of 2.4 to 4.4. The incidence of multiple household infections was related to the number of household members under 18 years of age and to the annual attack rate in the general population. The time interval between the onset of the initial and subsequent cases in a household followed a characteristic pattern; most of the cases occurred within the first week, about 95% within two weeks, and 99 to 100% within five weeks. The percentage of cases after the first week seemed to be somewhat higher among persons between the of 15 and 34 than among those under 15. The incidence oliomyelitis in household contacts after the onset of the index case was about 40 times greater than that of the general population. It was proportionately greater between 15 and 34 than below 14 years of age. In the group from 15 to 34, the frequency of bulbar poliomyelitis and the mortality were also increased.

Surgical Aspects of Thyrotoxic Heart Disease.—According to Schlicke and Delaney the following cardiovascular problems are encountered in thyroid surgery: (1) operations on the thyroid in the presence of serious but unrelated cardiovascular diseases; (2) cardiac disease first appearing in the postoperative period following thyroidectomy; and (3) the management of the so-called "thyrocardiacs." Among 200 patients undergoing thyroidectomy at their clinic, 33 presented cardiovascular problems. The manner in which the thyroid may affect the heart is quite clear in some respects, rather obscure in others. There is the myxedema heart of thyroid failure. There is the so-called "mechanical goiter heart" of Rose in which a huge goiter by its sheer bulk seems to embarrass the circulation. There is the group of cardiac disorders associated with the thyrotoxic state. Cardiac muscle metabolism increases as does that of other tissues, but in addition thyroxin exercises a direct effect on the myocardium; also there may be stimulation of the accelerator fibers of the sympathetic nervous system. The decision of whether a coexisting goiter is coincidental or causative may be difficult. Occasionally a trial of therapy with iodine or one of the antithyroid drugs may be helpful, although the response of adenomatous goiters is unpredictable. The failure of symptoms, such as tachycardia, arrhythmia, and signs of congestive failure, to respond well to therapy in a patient who is past the age of 50 and who has had a long period of disability and, often, weight loss is presumptive evidence pointing to a goiter of more than coincidental interest. The authors emphasize that every patient with heart disease should be carefully studied to exclude thyrotoxicosis. When thyrotoxicosis is found to exist, thyroidectomy should be carried out.

Results of Combined Orchiectomy and Estrogen Therapy in Cancer of Prostate.—Holder reviews observations on 139 patients with cancer of the prostate, who were treated at the University Clinic in Heidelberg, between 1943 and 1951. Fifty-six men were subjected to palliative treatment; 16 were treated with estrogen only, and 67 were subjected to bilateral orchiectomy plus estrogen therapy. During the first three or four years, when the palliative treatment was employed, the patients were subjected to transurethral electroresection or a suprapubic bladder fistula. These surgical interventions were often followed by roentgen irradiation. In the majority of the cases this treatment did not relieve pain, and death followed after an average period of about one year. Later, estrogen therapy was used for a time, and finally orchiectomy was combined with estrogen therapy. The group treated only with hormones is too small for statistical evaluation, but none of these patients survived longer than three years after the beginning of therapy. The third group, those who were treated by castration plus hormone therapy, showed the most favorable results: Thirty-six of these 67 patients had bone metastases. Twenty-eight patients have died, including 19 with bone metastases. Of the 39 survivors, 17 have metastases in the skeletal system (pelvis and vertebral column). Sixteen of these 39 patients are still able to work, despite the fact that 9 of them have extensive bone metastases. Supplementary electroresection was necessary in 9 of the 67 patients to counteract residual urine. The four patients who survived five or six years and of whom three have metastases had been treated for one or two years only with estrogens before orchiectomy was done. This would seem to indicate that immediate castration might not be necessary but that the patients can first be treated with estrogens. A definite statement on the average survival of these 67 patients subjected to castration plus estrogen therapy is as yet impossible, since 39 are still alive. The life expectancy of patients with carcinoma of the prostate is much greater now than before the period of antiandrogenic therapy.

Is Fulminant Pulmonary Embolism Meteorotropic?—A number of observers have presented data indicative of a relationship between fulminant pulmonary embolism and certain meteorologic events. Berg points out that some of these reports are contradictory. His own studies were based on extensive material from a relatively large geographical region; his studies were based on necropsy reports of 15 pathological institutes in western Germany. Data on 4,241 fulminant pulmonary embolisms that occurred between the years 1929 and 1952 were correlated with information obtained from the corresponding meteorologic charts. These studies revealed that "group formation" of embolisms is not demonstrable either in a single locality or in western Germany as a whole. The term "group formation" signifies an incidence considerably exceeding accidental concurrence of embolisms with certain meteorologic changes. It was found that the occurrence of a number of embolisms on the same day or on succeeding days did not occur more frequently during meteorologic changes than at other times during the period of observation. There is no seasonal difference in the frequency of embolisms, but there is a greater frequency of embolisms during certain hours of the day; that is, they are most frequent at 7 and 11 a. m. and at 4 and 8 p. m. The smallest number occurs around midnight. The greatest incidence at these hours is regarded a result of greater mobility and exertion of the patients at these times and particularly a concurrence with meal times. There is no connection in west Germany between the occurrence of fulminant pulmonary embolism and the passage of cold or warm fronts or with the occurrence of thunder storms. There is also no established connection between the occurrence of fulminant embolism and solar disturbances.

Pulmonary Thrombosis and Unexpected Death in Childhood.—Emery reports on pulmonary vascular thrombosis in 15 children seen in a series of 200 consecutive necropsies. The material consisted of routine necropsies at two children's hospitals and also cases referred through the coroner. A particular necropsy method was used in an attempt to leave fluid and inflammatory exudates in the respiratory passages in their natural position. Cases were included only when no sepsis was found in the lungs. The 15 children fell into four groups. 1. There were two severely debilitated neonatal infants. 2. In four children the thrombosis was the terminal incident in children with chronic disease. 3. Five children were admitted to hospital with acute severe dyspnea. 4. The last four children had been referred to the coroner, because they were found dead of unexplained causes. The author feels that the pulmonary thrombosis was probably not the primary cause of death in these children. The presence of antemortem thrombi and of alveolar edema suggests that the lesion was the terminal incident. Those children having symptoms before death suggest that the pulmonary thrombosis was a major factor in death. In the children who were observed in the hospital before the onset of pulmonary thrombosis, symptoms included pyrexia and dyspnea showing no response to antibiotics. Many of these children had a history of loose stools and vomiting, that is, increased loss of fluid from the body. This suggests that hemoconcentration and increased viscosity of the blood may have been a factor in the formation of the thrombosis. If an ill child develops unexpected pyrexia and dyspnea associated with loose stools or vomiting, venous thrombosis should be considered, and anticoagulant therapy is indicated, particularly if there is no response to antibiotics. In commenting on the sudden deaths referred to the coroner, the author says that since the decline in popularity of "status thymaticus" the most popular finding in these unexpected deaths has been that of microscopic evidence of upper respiratory infection. Such microscopic inflammatory foci were present in the four cases reviewed here, but in no greater degree than is seen in other children with otherwise adequate causes of death.

Treatment of Obstruction of Veins. H. M. Namo and H. Gofanovich Baron.—p. 70.

Rubellar Embryopathy.—Cataract, buphthalmus, and rubellar pigmented retinitis are serious malformations. They appear either alone or combined. Cataract is the most prominent symptom of rubellar embryopathy. It is bilateral in three out of four cases. It is frequently associated with microphthalmus, atrophy or coloboma of the iris, nystagmus, convergent strabismus, and opacities of the cornea. Buphthalmus is of great diagnostic importance when it is associated with a congenital cataract. As a rule, it is bilateral and often associated with papillary erosions. The intraocular pressure is moderately increased but can reach amounts as high as 100 mg. on the Schiötz tonometer. Rubellar pigmented retinitis can be differentiated from nonrubellar and other forms of retinitis. It occurs in unilateral retinitis or when the eye is aphakic after the operation. Other abnormalities such as coloboma of the choroid and opacities of the vitrium are less important. Rubellar nonocular malformations include deafness and cardiac malformations, the most frequent of which are the patent ductus arteriosus and abnormal communication between the ventricles or the auricles. Other abnormalities are dental malformations, microcephaly, hydrocephaly, mental disorders, inversion of the cycle of sleep, and *Franceschetti's digito-ocular sign, in which the infant* makes pressure on the eye with his thumb and index finger. Certain somatic and visceral malformations can also be observed. The authors report eight cases, seven in infants and one in a woman of 22 years of age. The mothers of these patients had rubella between the first and third months of pregnancy. Cataract was bilateral in four cases and unilateral in four. In the group of four patients with bilateral cataract, three had microphthalmia and one buphthalmus. Rubellar pigmented retinitis was observed in two cases of unilateral cataract.

Primary Carcinoma of Liver.—Liu discusses observations on 19 autopsied cases of primary carcinoma of the liver, which were observed among 2,424 autopsies on Chinese persons. Since this disease is regarded as commoner among oriental races than among Europeans or Americans, autopsy reports on all non-Chinese were disregarded as were autopsy reports on children less than two years old. The author believes that the difference in incidence is probably due to environmental *factors, more specifically, dietary habits, rather than to* any racial predisposition. Seventeen of the 19 cases were in men. Age incidence was highest between 40 and 60 years. Evidence obtained in this study supports the view that cirrhosis of the liver is an important predisposing factor in liver cell carcinoma. *Sixteen of the 19 patients had nodular cirrhosis,* and three had biliary cirrhosis. It seems probable that biliary cirrhosis is secondary to the obstruction of the biliary system. Pathological studies disclosed that 13 of the 19 patients had hepatoma, 3 had cholangioma, and 3 had "hepatocholangioma." In view of the common embryonic origin of both hepatic and bile epithelia, the presence of glandular structures in hepatomas is probably the result of divergency of cellular differentiation and thus the "hepatocholangiomas" need not be separately classified.

**Eight Cases of Acute Tetrachlorethane Poisoning. J. B. Sherman.*—p. 139.

Acute Poisoning with Tetrachlorethane.—Tetrachlorethane used as a solvent is one of the most toxic of the chlorinated hydrocarbons. The accident here reported was due to confusion with tetrachlorethylene, which it resembles not only in name, but also in odor, and to the fact that tetrachlorethane was not labeled "poison." Eight adults were given at 10:30 a. m. 3 ml. of tetrachlorethane (under the impression that it was tetrachlorethylene) plus 1 oz. (30 gm.) of magnesium sulfate and water. Three were inpatients, but the remainder went home. At 12 noon one inpatient suddenly became comatose. All superficial reflexes were absent, and the pupils were enlarged and fixed. The pulse was barely perceptible. Respirations were very shallow and rapid. The breath smelled of what was thought to be tetrachlorethylene. An enema was given and methedrine injections at 15 minute intervals. After about *half* an hour the patient regained consciousness but complained of headache. By this time, the other two inpatients were in deep coma, and similar treatment was being given them. Search for the ambulatory patients found them in various stages of semiconsciousness. All were brought back to the hospital, but after an hour they insisted that they were well. All were watched for three months, and no untoward effects could be detected. As the untreated patients recovered as rapidly as the treated ones, it seems that the treatment given had small effect. Perhaps the magnesium sulfate helped elimination via the bowel. In view of the fact that such dramatic results ensued after a dose of 3 ml., Sherman believes that 4 to 5 ml. would have been fatal. This agrees with Elliott's contention that 5 ml. is the lethal dose for an adult.

Glucagon, the Hyperglycemic Factor of the Pancreas.—De Duve cites evidence that insulin is not the only endocrine principle secreted by the pancreas, but that the pancreas also contains a highly active and specific glycogenolytic polypeptide that originates in the alpha cells of the islets and that can act as a powerful insulin antagonist. He also gives evidence that an alloxan-resistant part of the pancreas, probably not the acinar tissue, secretes into the blood stream a substance that raises the blood sugar level, lowers the glycogen content of the liver, and decreases the effectiveness of insulin. The hyperglycemic factor of the pancreas was referred to in the early work as "glucagon," a name proposed by Kimball and Murlin in 1924. In some countries this term has been retained, but it has been superseded in much of the recent work by "hyperglycemic glycogenolytic factor," H.G. factor, or H.G.F. De Duve points out that Ferner suggested in 1951 that metabolic equilibrium is achieved by a balance between the two opposed pancreatic secretions insulin and glucagon; any large increase of one over the other leads to either spontaneous hypoglycemia or diabetes. An islet adenoma containing predominantly beta cells causes spontaneous hypoglycemia, and the destruction of the beta cells leads to diabetes. The diabetic state that follows the total removal of the pancreas, and its alleviation by hypophysectomy, can be partly explained on the basis of this concept, since active alpha cells remain in the gastric mucosa of dogs subjected to pancreatectomy and may be stimulated there by the growth hormone. Glucagon has become an important factor in considerations of the etiology of diabetes, and many concepts on the interrelationships between the endocrine glands will need to be revised in the light of the new knowledge. There is now a body of mutually confirming data indicating that glucagon is the long-sought hormone of the alpha cells of the pancreatic islets and that glucagon is involved in the physiological regulation of metabolism and, presumably, of growth.

*Tuberculous Meningitis Developing During Streptomycin Therapy That Cured Tuberculous Pericarditis. G. Aceto.—p. 257.

Tuberculous Meningitis After Recovery From Tuberculous Pericarditis.—Tuberculous meningitis occurred in an 8-year-old boy who had recently recovered from tuberculous pericarditis. The father, 32 years old, had been cured of pulmonary tuberculosis the year before. Besides the diseases of childhood, the child had suffered a tuberculous cervical adenitis at 12 months and a tuberculous coxitis cured without streptomycin at 16 months. At admission the child was in poor general condition with a history of evening fever, vomiting, and dyspnea of eight days' duration. Chemically the urine was normal, but microscopic examination revealed numerous calcium phosphate crystals. The tuberculin reaction was slightly positive. Radioscopy of the chest revealed exudative perilymphadenitis on the left side. Telecardiograms and electrocardiograms showed exudative pericarditis and an enlarged heart. Three successive pericardicenteses two days apart yielded 360 cc. of exudate. At the same time streptomycin was introduced into the pericardium (0.30 gm. in three times), and the boy was given calcium, vitamins, and *p*-aminosalicylic acid. Microscopic examination of the exudate revealed a predominance of lymphocytes with a small number of erythrocytes; staining revealed tubercle bacilli. Roentgenograms taken 24 hours after the last pericardicentesis showed that the heart had diminished to half its initial size. Two weeks later intrapericardiac exudate was no longer present. The boy was euphoric, could sit up, and had gained 400 gm. in weight. Systemic streptomycin therapy was continued despite this recovery. On the 13th day of therapy the child complained of a mild headache, which became severe during the night. A mild nuchal rigidity, cerebral vomiting, and frank anisocoria also appeared. Both Brudzinski's signs being positive, spinal fluid was withdrawn, and a diagnosis of tuberculous meningitis was confirmed. Streptomycin was given daily by the lumbar, cisternal, and intramuscular routes according to Cocchi's schedule and was combined with administration of *p*-aminosalicylic acid, vitamin A, and cardiokinetic drugs. The boy's general condition became worse; generalized tonic and clonic convulsions, cyanosis, bradycardia, and alternating mydriasis and miosis developed, and the patient died four days later. According to the author, the primary focus was in the pulmonary parenchyma, probably on the left side, and the lymphadenitis, coxitis, pericarditis, and meningitis were all episodes of hematogenous dissemination of the condition.

*Therapy of Hypertension with Hydrazinophthalazine Preparations. P. Kummer and R. von La Rosée.—p. 729.

Hypertension: Treatment with Hydrazinophthalazine Preparations.—Kummer and von La Rosée present their experiences with phthalazine derivatives in 32 patients with hypertension. Instead of the widely used hydralazine hydrochloride (Apresoline), they used mostly Nepresol (1,4-dihydrazinophthalazine). They preferred this latter preparation, because they became convinced that it had a somewhat more subdued and protracted effect than hydralazine and that it was tolerated better. The preparation was used in 32 patients, including 19 with essential hypertension, 2 in whom the hypertension led to nephrosclerosis, 3 with malignant sclerosis, 2 with pyelonephritis, 4 with chronic nephritis, and 2 with pregnancy nephropathy. These patients were first subjected to general measures, such as bed rest, salt-free diet, barbiturates and strophanthin, and then treatment with the phthalazine preparation was begun. It was found that when the medication with the phthalazine had been suitably individualized, about two-thirds of the patients showed a satisfactory reduction in blood pressure. The maximal reduction in systolic pressure was 80 mm. Hg and in diastolic pressure up to 40 mm. Hg. The blood pressure reducing effect was more extensive, the higher had been the pulse pressure before treatment and the lower had been the values for the elasticity coefficient and the peripheral resistance to circulation. The pulse pressure regularly decreased under the influence of the drug. The elasticity coefficient and the resistance did not show uniform behavior but in general showed a tendency to increase. The clinical changes indicated that the regulatory centers in the central nervous system had been acted on by the drug, possibly by a centrally regulated increase in venous stasis. The reduction in the blood flow of the kidneys was relatively slight in comparison with the reduction in the pulse pressure, and this probably explains why signs of renal insufficiency rarely increased. This occurred only in patients who already had renal decompensation. The undesirable secondary effects resulting from the Nepresol consisted mostly of headache, blurred vision, visual disturbances, vertigo, and palpitation. Electrocardiographic studies on patients with signs of stenocardia showed reductions in the ST deflection and flattening of the T-wave. Most secondary effect could be controlled with antihistamines and other measures. The authors conclude that the phthalazine derivative, Nepresol, is the preferred drug in the treatment of hypertension.

Determination of Bleeding Time. S. I. de Vries.—p. 1595.
Natural Cowpox in Man. F. de Stoppelaar.—p. 1602.

Cortisone in Treatment of Gold Dermatitis.—Den Oudsten and van Schouwen present histories of two patients who received gold treatment for rheumatoid arthritis. In the course of this treatment severe cutaneous, erythematosquamous eruptions appeared. There was severe itching and some ulceration. Under the influence of cortisone treatment the skin eruption subsided. The advantage of cortisone over dimercaprol (BAL) is that cortisone does not mobilize and promote the excretion of gold. Thus the gold remains in the body and exerts its antirheumatic effect, after the dermatitis has been counteracted.

Fatal Aplastic Anemia After Prolonged Treatment with Chloramphenicol.—A 56-year-old man had, for about 12 months, been taking daily a small dose of chloramphenicol. He had taken the drug on his own initiative to counteract his "smokers cough." When cutaneous hemorrhages developed, he asked medical advice, and pancytopenia was diagnosed. Despite various therapeutic methods, including blood transfusions and cortisone and corticotropin to counteract the pancytopenia, the patient died. The authors point out that this serious complication of chloramphenicol treatment has been repeatedly observed, particularly, when use of the drug was not actually indicated.

*Cirsoid and Arteriovenous Aneurysms of the Brain (19 Cases). Anatomical, Clinical, and Radiological Considerations. D. Petit-Dutaillis, G. Guiot and H. Berdet.—p. 901.
Diagnosis and Treatment of Malignant Tumors of Kidney in Children. R. Huguenin and R. Gérard-Marchant.—p. 909.
*New Technique for Bronchography: Lipiodol Vaporization. J. Girard, J.-P. Grilliat, R. Senot and P. Faucompre.—p. 914.

Cirsoid and Arteriovenous Aneurysms of the Brain.—Cirsoid aneurysms, which are vascular malformations characterized by a rarity or absence of capillaries and by extensive multiple communications between their arterial and venous elements, should be distinguished from arteriovenous aneurysms, in which the intervascular communication is either direct or takes place through an abnormal arteriolar tuft or a small area of telangiectasis. Transitional forms are numerous, and the surgical problem presented varies in each case according to the type of the lesion. Increasing use of arteriography at the Clinique de la Pitié led to the discovery of 18 cases in the last four years; of these, 16 were supratentorial. Clinical symptoms are noncharacteristic, but the presence of an aneurysm should be suspected when a patient has attacks of focal epilepsy, either alternating with or accompanied by meningeal hemorrhage. Five of the patients in this series also had angiomas of the skin or mucous membrane. Signs of spontaneous cerebral hematoma in a young patient likewise suggest the existence of an aneurysm; arteriography in such cases will establish the diagnosis by showing both the aneurysm and the hematoma, which is evidenced by displacement of the anterior cerebral artery or the sylvian artery. Thorough arteriographic study of these lesions is essential for both correct diagnosis and successful surgical treatment.

New Technique in Bronchography: *Lipiodol* Vaporization.—Iodized oil (Lipiodol) vaporization eliminates or reduces many of the difficulties formerly encountered in bronchography. Complete saturation of the bronchial tree is obtained by using a mixture of one-third heavy iodized oil in a 40% concentration with two-thirds fluid iodized oil (Lipiodol "F") also in a 40% concentration. The patient is given 20 cg. of phenobarbital (Gardenal) and ¾ mg. of atropine 15 minutes before anesthesia is started; a small dose of an opiate or an antihistamine may also be useful in some cases. Anesthesia, which need not be deep, is induced with 0.5% tetracaine (Pantocaine), often by the nasal route. A special double-tube catheter is then introduced through either the mouth or the nose, and the iodized oil mixture is vaporized as needed (6 cc. will saturate one lung); complete saturation is obtained by a series of postural changes during vaporization, which lasts three minutes at the most; and the films are taken at once. The fine layer of iodized oil deposited shows all the bronchial contours and brings out even the slightest anomalies in the mucosa. The small amount of the mixture used facilitates its rapid elimination from the lungs and permits its use even in patients with active tuberculosis. This method may be used for aged patients and those in poor condition. It does not cause shock, and the toxic effects of the iodine are reduced. The ventilatory capacity of the lungs is maintained throughout the procedure, and no complications have accompanied its use so far.

Treatment of Gout. F. Coste.—p. 179.
Respiratory Infections in Genesis of Rheumatism. J. Turiaf.—p. 184.
Cellulitis. F. Françon.—p. 191.
*Use of Hydrocortisone in Present Rheumatological Practice. A. Rubens-Duval.—p. 193.

Use of Hydrocortisone in Rheumatic Conditions.—Hydrocortisone acetate given intramuscularly in chronic progressive polyarthritis is slightly less effective than cortisone but has the advantage of not causing salt or water retention or psychic disturbances. Alcoholic hydrocortisone given orally, on the other hand, is superior to cortisone given orally in the same doses. Improvement not only comes earlier, but is more complete and is entirely free from disagreeable side-effects. Maintenance doses may also be much smaller (approximately 40 mg.). These differences in action may be explained by differences in the solubility of the drugs in plasma. Alcoholic hydrocortisone is four times as soluble as cortisone and 28 times as soluble as hydrocortisone acetate; its diffusibility is, therefore, greater, and this explains the rapidity and efficacy of its therapeutic action. Hydrocortisone acetate, because it is less soluble and does not spread so rapidly, is especially useful in the local treatment of inflammatory joint reactions. Intra-articular injection of 25 mg. will often be followed within 12 to 24 hours by diminution of the local inflammatory phenomena, especially pain, permitting wider mobilization of the joint. The improvement usually lasts for four or five days. Habituation does not occur, and each new injection is followed by relief. Functional results depend largely on the condition of the joint; prognosis is poorer when fibrosis is present, but relief of pain facilitates movement and makes physiotherapy possible. Hydrocortisone therapy of chronic progressive polyarthritis is limited by the need for repeated injections and the number of joints requiring treatment; it should be used chiefly to overcome residual articular inflammation resistant to general therapy, to secure mobilization of a stiff joint, to correct malposition, or to make it possible to reduce cortisone dosage in patients with impending metabolic disturbances caused by therapy. Hydrocortisone has given excellent results in other forms of arthritis and in arthroses of the knee and shoulder. Rigorously aseptic technique must be used in injecting the drug, and in some cases antibiotics should be used to lessen the danger of reactivating an infectious process.

BOOK REVIEWS

Toxic Hazards of Certain Pesticides to Man. By J. M. Barnes. Together with select bibliography on toxicology of pesticides in man and mammals. World Health Organization, monograph series no. 16. Paper. $1.50; 7/6; 480 French francs; 6 Swiss francs. Pp. 129. World Health Organization, Palais des Nations, Geneva; Columbia University Press, 2960 Broadway, New York 27, 1953.

This small volume is the formal report of an international study undertaken by the author on behalf of the World Health Organization, of chemicals used in agriculture and public health activities that present a clear and immediate danger during manufacture, application, or when present as residue on food. The report itself comprises only one-third of the volume; the remainder is composed of an extensive bibliography and appendixes on toxic properties, nomenclature, and legislative control of agricultural chemicals in North American and several European countries. The report is divided into several sections, including discussions on the use of pesticides in disease control and crop protection; hazards and their control during application, in manufacture, and to those not directly involved with handling of the agents; suggestions and recommendations for research; and general conclusions. The report is well written and may be of value as a reference source to public health officials and others concerned with the toxic hazards to man of pesticides.

Tumors of the Orbit and Allied Pseudo Tumors: An Analysis of 216 Case Histories. By Raymond G. Ingalls, M.D. Cloth. $11.50. Pp. 410, with 140 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Illinois; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This book consists of an analysis of data obtained from the study of 216 orbital tumors, of which there were 27 types classified into three main groups: primary, secondary invaders, and tumor-like lesions. The greater part of the data is derived from photographs, biopsy specimens, and case histories of orbital tumors originally assembled for exhibition at the 1947 meeting of the American Academy of Ophthalmology and Otolaryngology. The exhibit illustrated the important features of orbital tumors with pictures of the patient with unilateral exophthalmos, case histories, microscopic description of the tumor, and the end result. For each tumor the author describes the etiological factors, anatomic locations, shape, consistency and color, symptoms, amount of limitation of ocular motility, and relationship between the visual acuity, exophthalmos, and fundus changes. By means of certain statistical tables, one of which is entitled "Age Factor in Orbital Tumors," the ophthalmologist is given considerable help in differential diagnosis of orbital tumors. In the chapter on pseudo tumors, the author very properly points out that the removal of the entire mass not only is undesirable but may result in the loss of considerable muscle tissue with later serious limitation of motility. In view of this untoward result it is now the practice to limit the excision to biopsy proportions only.

By including reports from the recent literature as a supplement to each chapter, the author is able to keep his book up-to-date. From the standpoint of readability, the book is very well arranged, the quality of paper is excellent, and the type is large and well set. The arrangement of photographs and charts is also well done. All of these factors make for easy and smooth reading. Whether the ophthalmologist is associated with a large private institution, a large charity clinic, or in the private practice of ophthalmology, this book will be of inestimable value to him when he meets the patient with unilateral exophthalmos.

Sectional Radiography of the Chest. By Irving J. Kane, M.D., Consultant in Chest Diseases, United States Naval Hospital, St. Albans, N. Y. Foreword by Edward D. Churchill, M.D. Cloth. $7.50. Pp. 154, with 101 illustrations. Springer Publishing Company, Inc., 44 E. 23rd St., New York 10, 1953.

In the 20 years since the work of Ziedses des Plantes, planigraphy has come to occupy a small but important place as an adjunct to ordinary radiography in detecting and localizing cavities in the lungs. Dr. Kane, an internist specializing in diseases of the chest, obviously draws on a large clinical experience for his discussion of thoracic anatomy and pathology as portrayed by planigrams or, as he prefers to call them, sectional radiographs. All of his 80 reproductions are of good quality, and there is a useful bibliography of 180 items.

In pages 35 to 41 the author deals with technical matters in which he appears to be less well informed, and his figures 8A and 10A of page 41 embody important errors. It is true that almost any commercial exposing table and tube stand can be modified to do planigraphy, and it is true also that it is not essential to tilt the tube if one is willing to use a sufficiently short tube-film travel and a sufficiently large tube cone. It is a simple matter to tilt the tube, however, and it is highly desirable to use the smallest cone that will cover the film to assure minimum blurring by scattering and minimum unnecessary irradiation of the patient's tissues. In the two figures referred to above, the artist has shown a tube-film travel obviously much larger than that actually employed by Dr. Kane in making the respective planigrams. Radiologists will understand the point and not be misled by the figures, but other physicians who, having read this book, were to decide to equip themselves to do planigraphy would be disappointed if they tried to follow the plan outlined in these figures. Those who do planigraphy would be well advised to employ commercial rather than homemade equipment, to tilt the tube, and to use small rectangular cones that barely cover the film.

Clinical Orthopaedics. Number One. Anthony F. DePalma, editor-in-chief. With assistance of five associate editors and board of six advisory editors. Cloth. $6; sustaining $5. Pp. 242, with 149 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

This work is designed for the publication of original articles dealing with orthopedics and is sponsored by the Association of Bone and Joint Surgeons. The editor believes there is a need for additional outlets for material of orthopedic interest. He feels that the existing journals cannot publish much of the worthy material because of a lack of space. As a result of this, these works are published in journals dealing primarily with general surgery and are therefore lost to those to whom they would be of most interest. The sponsors of this work hope that they can provide a publication whereby this material can be disseminated not only to the orthopedic surgeon but also to those who are in ancillary specialties, and particularly to the general practitioner. At present, two issues a year are contemplated. These are essentially divided into two parts; the first is devoted to the consideration of a specific topic, and the second will contain miscellaneous articles dealing with orthopedics and allied subjects. Section 1 of this volume deals with children's orthopedics and section 2 with general orthopedics. Special commendation should be given those articles that consider infantile scurvy, structural scoliosis, and treatment of poliomyelitis based on pathophysiology. The format of this number is good, the figures have reproduced well, and a good-sized type placed in double column makes for easy reading. This work can be recommended to anyone interested in orthopedics and associated topics.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

Tumors of Bone: A Roentgenographic Atlas. By Bradley L. Coley, M.D., F.A.C.S., Attending Surgeon, Bone Service, Memorial Center for Cancer and Allied Diseases, New York, and Norman L. Higinbotham, M.D., C.M., F.A.C.S., Associate Attending Surgeon, Bone Service, Memorial Center for Cancer and Allied Diseases. Annals of Roentgenology, Volume XXI. Cloth. $10. Pp. 216, with 172 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

Continuing a policy laid down by the publisher many decades ago, this volume attempts to be at once a monograph and an atlas describing and illustrating some of the more important skeletal neoplasms and certain non-neoplastic lesions that simulate them. However useful it may have been to supply the physicians of an earlier generation with sample radiographs of proved cases of various diseases, certainly the approach has been outmoded and is not what one expects to find in a present-day book on bone tumors.

The introduction quite properly stresses the fact that radiology and gross and microscopic pathology cooperate rather than compete in the diagnosis of bone tumors. Unfortunately, however, there is no discussion of terminology, so that in the 73 pages dealing with primary malignant neoplasm one has only the arrangement of the material to indicate just what conditions the authors intend to include under specific headings; for example, the inclusion of figure 8 among the osteogenic sarcomas suggests that the authors consider fibrosarcoma to be a subdivision of osteogenic sarcoma, but presumably case 23 (osteoid osteoma) was included among the osteogenic sarcomas merely for comparison.

Figure 21 and the statement on page 4 relative to osteogenic sarcoma developing in myositis ossificans may lead readers to the erroneous and dangerous conclusion that the acute traumatic myositis ossificans that is rather frequently encountered in the thigh muscles of young football players is a potential source of osteogenic sarcoma.

Lacking are discussions of tumor bone versus reactive bone; the role of Sharpey's fibers in producing the "sunburst" pattern, long misinterpreted as typical tumor bone; and the necessity and safety of taking large biopsy specimens. In the discussion of metastases no reference is made to the tendency of those from osteogenic sarcoma to produce bone, and the legend for figure 26 might be misinterpreted as indicating that spherical pulmonary metastases are peculiar to osteogenic sarcoma. In the legend for figure 62 the authors doubt the possibility of clinical cure in solitary plasma cell myeloma, but such cases are mentioned in the literature. The book includes several illustrations of osteoid osteoma, but the authors do not describe the gross lesion or refer to the central dense fleck that is occasionally seen at the center of the negative shadow. In the legend for figure 99 the authors are correct in stressing the unlikeliness of malignant degeneration in benign enchondroma of the finger bones, but such degeneration does sometimes occur. The authors are competent and experienced, but 200 pages are too few and the atlas form is ill suited to the task they undertook. They would have produced a better book if they had narrowed the field so that they might deal more exhaustively with a few types of bone neoplasm.

Nervous Transmission. By Ichiji Tasaki, M.D. Cloth. $7.50. Pp. 164, with 77 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

An especially interesting chapter in this book explains the techniques now used to study the electrical phenomena in single motor nerve fibers. These experiments lead to reconsideration of the idea of decrement conduction in narcotized fibers, which has inspired much research, and to further elaboration of the idea of saltatory transmission from one node of Ranvier to the next. The supposed absence of these nodes in the myelinated fibers of the brain and cord formerly posed a difficulty, which has been removed by recent reports of their presence at least in the spinal cord.

The text makes good reading in places where the material is concrete and "operational" but becomes difficult, sometimes unnecessarily so, in the abstract and mathematical portions. The difficulty is occasionally traceable to words like "nonlinear" (page 149), for the ambiguity of which the modern mathematician is to blame. The reader is not always sure that the author intends to make apparent distinctions, such as that between potential difference and electromotive force (page 146). If the conscientious student notes that proper names are capitalized, as in Wheatstone bridge (page 8), what is he to deduce from the spelling "ringer fluid" (page 9)? In view of the long-continued deprecation of eponymic phrases like sheath of Schwann, the student wonders why the author does not write neurilemma. Obscurities of this sort are so frequent in the scriptures of axonology and mathematical biophysics as to justify the question whether they are intended to be understood or just to impress. An individual author therefore is perhaps not to blame for compromising between clarity and tradition. The bibliography is accurate, and the index has been carefully prepared. The book will be important to students and teachers of neurophysiology.

Statistical Methods in Experimentation: An Introduction. By Oliver L. Lacey, Professor of Psychology, University of Alabama. Cloth. $4.50. Pp. 249, with 33 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1953.

This compact and attractive book is intended as an introduction to the subject for students who have completed a semester of college algebra. Its best feature is a remarkable collection of problems from physiology, anthropometry, psychology, industry, and even politics, which cannot fail to impress students with the importance of the subject and the diversity of forms in which statistical problems present themselves.

Diseases of Children. Volumes I and II. Edited by Alan Moncrieff, C.B.E., M.D., F.R.C.P., Nuffield Professor of Child Health, University of London, England, and Philip Evans, M.D., M.Sc., F.R.C.P., Physician to Children's Department and Director of Department of Child Health, Guy's Hospital, London. With contributions by fifty contributors. Previous editions edited by Sir A. E. Garrod, K.C.M.G., D.M., F.R.S., Frederick E. Batten, M.D., M.A., F.R.C.P., Hugh Thursfield, D.M., M.A., F.R.C.P., and Donald Paterson, M.D., F.R.C.P. Fifth edition. Cloth. $21 per set. Pp. 1014; 1015-1973, with 690 illustrations. [Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2]; Edward Arnold & Co., 41-43 Maddox St., London, W.1, 1953.

This book is the fifth edition of Garrod, Batton, and Thursfield's pediatric textbook. The present edition, capably edited by Moncrieff and Evans, contains contributions of 50 highly qualified authors drawn from both Britain and America. The text appears to represent an attempt to accomplish as complete coverage of the field of pediatrics as is possible without providing an exhaustive review of pediatric literature. Since the last edition was published, in 1947, the book has been brought up-to-date and altered to meet demands of an expanding field. That emphasis has been placed on progress is signaled by the introduction of completely new chapters on growth and development, causes of congenital malformations, use of drugs in pediatrics, pediatric endocrinology, and congenital heart disease, as well as the extensive revision of most of the other chapters. The text is well illustrated.

The two volumes are divided into three main sections. The initial subdivision contains nine chapters and deals with general considerations basic to the skillful, scientific care of children. This section contains chapters on vital statistics, heredity, causes of congenital malformations, growth and development, water and electrolyte control and acid base regulation, clinical pathology, drug therapy, anesthesiology in infancy, and infant feeding. The chapters in this section, in general, are concise, factual, and up-to-date. The entire section provides a good background for a departure into pediatrics.

The second section is divided into 28 chapters and occupies most of the book. It is devoted to the description of diseases of children and their management. The final section is an appendix in which numerous practical pediatric procedures are described. With the aid of 30 good illustrations, the techniques of blood letting, infusion, exchange transfusion, bone marrow aspiration, collection of urine, and many other useful pediatric procedures are lucidly presented. The index, though not outstanding, is adequate. As a textbook of pediatrics for students and as a rapid reference book for pediatric practitioners this edition compares favorably with the best of the current American textbooks of pediatrics.

Nomenclature and Criteria for Diagnosis of Diseases of the Heart and Blood Vessels. By Criteria Committee of New York Heart Association, Inc., Harold E. B. Pardee, M.D., Chairman. Fifth edition. Cloth. $4.95. Pp. 359, with 51 illustrations. New York Heart Association, Inc., 270 Park Ave., New York 17; distributed by American Heart Association, 1775 Broadway, New York 19, 1953.

This edition deals with the nomenclature and classification of heart diseases and is supplemented by discussions of criteria for diagnosis. It has been considerably expanded to include a section on diseases of the peripheral vessels. It introduces changes of opinion and viewpoints that have taken place in the past 10 years. Important etiological factors in cardiac disease have been amplified. The criteria for the diagnosis of congenital anomalies have been greatly expanded. The therapeutic classification, which proved so beneficial in former editions, has been continued. The roentgenological and electrocardiographic sections have been rewritten and new material added. The criteria for the pathological diagnosis of diseases of the heart and great vessels has been made an integral part of the book instead of an appendix as it was in previous editions. The terminology and coding in the section on nomenclature correspond completely with the Standard Nomenclature of Diseases and Operations.

This edition is an estimable guide to cardiologists and clinicians dealing with heart diseases. It is an excellent reference book for all medical record libraries and should be extremely valuable for teaching hospitals. The book is well printed, and the illustrations are clear.

Annual Review of Medicine. Volume 4. Windsor C. Cutting, editor; Henry W. Newman, associate editor. Cloth. $6. Pp. 452. Annual Reviews, Inc., Stanford, California; H. K. Lewis & Company, Ltd., 136 Gower St., London, W.C.1; Maruzen Company, Ltd., 6 Tori-Nichome Nihonbashi, Tokyo, 1953.

This book differs from previous editions in that it includes the writings of a number of international authorities who present thoughtful and readable presentations of advances made in their special fields. The topics selected for discussion will have a wide range of appeal to many readers who will find much useful information under such headings as infectious diseases, cardiovascular and gastrointestinal diseases, respiratory diseases, nutrition, hematology, diseases of the nervous system and psychiatry, anesthesia, radioactivity, toxicology, dentistry, public health, and physical agents and trauma.

Stress and Disease. By Harold G. Wolff, M.D., Professor of Medicine (Neurology), Cornell University Medical College, New York. Publication number 166, American Lecture Series, monograph in Bannerstone Division of American Lectures in Physiology. Edited by Robert F. Pitts, M.D., Ph.D., Professor of Physiology and Biophysics, Cornell University Medical College. Cloth. $5.50. Pp. 199, with 38 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

Many years ago there was a popular ditty that began like this: "Every little movement has a meaning all its own; every thought and feeling by some action may be shown." This common sense idea has been known to every good physician since the days of Hippocrates. Unfortunately it has recently been rediscovered and exploited by some medical showmen under the name of psychosomatic medicine, but the author of this book does not commit this error. This monograph attempts to portray the role played by the environment in modifying a wide variety of diseases. It also relates these modifications to the person's life history, particularly to those situations which have been, consciously or unconsciously, stress producing. It is, in effect, a compilation of some aspects of psychosomatic medicine although the author avoids the use of this term.

Most of the experimental work cited has been done by the author and many colleagues. It covers a large number of medical disorders, ranging through several organ systems, with special emphasis on the gastrointestinal tract, the circulatory system, the nervous system, and the skin. It contains several graphs, all of which are clear. Two figures that illustrate temporal artery pulsations seem to require reading from right to left, although this is not so stated.

The English style in parts of the book is somewhat obscure; for example, on page 34 is the sentence: "However, the investigations on man reported herewith show how radically form and function of structures may change during long standing yet even amazingly brief periods of strain."

Internists, general practitioners, and medical students would derive some stimulation from this volume although there are places where Dr. Wolff may have let his conclusions outrun his facts. There is a good bibliography, author index, and subject index.

Contact Dermatitis. By George L. Waldbott, M.D., F.A.A.A., F.A.C.A., Senior Physician, Harper Hospital, Detroit, Michigan. Publication number 133, American Lecture Series, monograph in Bannerstone Division of American Lectures in Dermatology. Edited by Arthur C. Curtis, M.D., Chairman, Department of Dermatology and Syphilology, University of Michigan, Ann Arbor. Cloth. $8.75. Pp. 218, with 131 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Avenue, Springfield, Illinois; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

Dr. Waldbott's plan of a profusely illustrated book with explanatory text was excellent in conception. The book has a large number of illustrations that were selected especially to demonstrate the value of studying the configuration of a contact dermatitis, for frequently the shape of an eruption will in itself point to the causative factor. There are over 131 illustrations of eruptions, many of which are most unusual, such as finger-tip dermatitis from a push button or telephone dial, and finger-band eruption from luggage, balls, or oranges. There is a large variety of patterns, for apparently the number of potential irritants encountered in every-day living is amazing.

The text, however, falls short of being the incisive work that might have been made of such interesting subject matter. The writing is repetitious, the material too often not pertinent to the subject, and in many cases the material is inaccurate. Such a statement as "the hemogram readily establishes the diagnosis of mycosis fungoides" (it is the histological picture on which the diagnosis is based) tends to destroy confidence in the book. But the illustrations and the various lists of cutaneous and occupational hazards are so useful as to make one wish that the text was more reliable and to hope that these weaknesses will be removed if the volume undergoes revision.

The Roentgen Aspects of the Papilla and Ampulla of Vater. By Maxwell H. Poppel, M.D., F.A.C.R., Professor of Radiology, New York University Post-Graduate Medical School, New York, Harold G. Jacobson, M.D., F.A.C.R., Director, Department of Roentgenology, Hospital for Special Surgery, New York, and Robert W. Smith, M.D. Cloth. $8.50. Pp. 195, with 106 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois; Blackwell Scientific Publications, Ltd., 49 Broad Street, Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

The authors set up criteria for the appraisal of the normal or abnormal major papilla and the ampulla of Vater and discuss the region of the Vaterian segment and surrounding organs. There are 83 illustrations from experimental studies of the major and minor papillae and 58 other excellent figures showing radiological findings and anatomic diagrams. Normal and abnormal papillae are well described and illustrated and are critically analyzed in an interesting manner.

The authors point out that the major papilla can be seen in one or more films of an ordinary gastric series showing the duodenum in about 50% of cases. No special technique and no unusual positions are required. As the authors state, "All that was necessary was a careful scrutiny of the Vaterian segment of the duodenum." There is good discussion of the embryology and physiology of the Vaterian segment. Congenital variations are graphically described, and associated pathological conditions are emphasized. The book is interesting and practical.

QUERIES AND MINOR NOTES

BRITTLE DIABETES

To the Editor:—*Please discuss the condition referred to as brittle diabetes in which there is marked fluctuation in the fasting blood sugar from day to day while the patient is on the same diet and same dosage of insulin.*

Frank C. Golding, M.D., El Paso, Texas

Answer.—Brittle diabetics, a term coined by Woodyatt, includes those diabetics who exhibit wide variations in glycosuria and glycemia without obvious causes, such as variations in the composition and absorption of the diet, exercise, insulin, and infections or alterations in the activity of the pituitary, thyroid, adrenal, or liver. The more accurately and critically the diabetic is studied, the less frequently such cases are encountered. They are, if anything, even less frequent than the 2% observed by Haunz (*J. A. M. A.* **142**:168 [Jan. 21] 1950) among 310 diabetics during a period of two years. Other recent references include those of Colwell (*Pennsylvania M. J.* **52**:1638, 1949), Lamar (*J. A. M. A.* **142**:1350 [April 29] 1950), and Baker and Colwell (*Proceedings of the American Diabetes Association* **8**:39-54, 1948). When Rollo in 1796 learned Captain Meredith had been exposed to apple pie the night preceding an unexplained finding of sugar in the urine, when Cantani forcefully demonstrated that his patients when under lock and key and fed 600 gm. of meat were sugar free, and when Bouchardat taught his patients that, if they found a food produced glycosuria by their own tests of their urine after eating it, that food contained too much carbohydrate for them, the explanation of most brittle diabetics was solved. The term brittle diabetes, like that of acute fulminating diabetes, will probably gradually drop out of the literature.

Scrupulous accuracy in computing the diet and uniformity in its absorption are far more difficult to attain today than formerly. Diets are now much larger and often contain more calories than required, and consist of much more carbohydrate in total grams, in variety, and in higher percentages. The estimation of the effect of exercise is less easy because the patients are no longer bedridden but are active; also, the exercise is more variable. Insulin greatly complicates the picture, because of errors in its measurement resulting from different strengths and varieties, technique of administration, absorption because of faulty injection in one site rather than in separate sites each day of the month and especially by injection into areas of lipodystrophy (fat hypertrophies and atrophies).

Tendencies to brittleness may be expected particularly in the young, the thin, the active, emotionally or otherwise, the uncooperative patient or the discouraged patient who has become careless and often thoughtlessly breaks regulations. Children, severe, and thin diabetics have a low storage capacity for glycogen. Variations, therefore, in total food, carbohydrate, exercise, and insulin lead to a more prompt response in the blood sugar, because the glycogen reserve is so low. Might it not often be 50 rather than 300 grams? The total fasting sugar in the blood of an adult weighing 70 kg. is less than 7 gm. (7,000 cc. blood × 0.1%) and in a child of 35 kg., 3.5 gm., or the equivalent of a small lump of sugar. The wonder is that the carbohydrate stored as glycogen and sugar in health and especially in diabetes can be so well controlled, especially when dependent on an artificial supply of insulin. Furthermore, as a rule only about 10 gm. of carbohydrate are oxidized an hour, a larger quantity usually being deposited either as glycogen or more likely converted into fat, thus adding to the complexity of the picture. For all these reasons it is probable that a standard caloric diet suited to the metabolic needs of the patient, containing about 150 gm. of carbohydrate, or even 100 gm. in a very small person, will lead to less variations in the blood sugar than one with 200 gm. or more. Adjustments must be made for exercise.

Insulin usually will be required at least twice a day, preferably NPH before breakfast and the evening meal, with additions to it of crystalline insulin as needed, morning and night. To remove apprehension, the patient can at first supplement the diet with carbohydrate in the forenoon, afternoon, and evening and in extreme cases 3 to 5 gm. an hour when the clock strikes, just as Sippy taught his ulcer patients to take their milk and cream at short intervals. Quantities of food can be increased easily, if exercise is increased. After the patient gains confidence, the administration of diet can be simplified. All agree that in such cases the three meals and three lunches should be spread over at least 12 hours, and one author even suggests that six injections of crystalline insulin be employed. Generally, two injections of NPH insulin with or without added crystalline insulin will suffice, along with careful adjustment of diet to the four daily tests of the urine. Lamar writes, "It is obvious that the neglect of a single detail in the instruction of these patients has made a great difference in their lives."

ATHLETES WITH DEFECTIVE VISION

To the Editor:—*I would like an opinion on the eligibility of high school boys for contact sports who have severe eye defects. Such defects include (1) a condition in which all vision has been lost in one eye but is normal or nearly so in the other eye and (2) a case in which vision is 20/100 in both eyes without glasses, and, as in football, protectors are not practical, and the boy apparently plays satisfactorily without glasses.*

M.D., New York.

This inquiry was referred to two consultants whose respective replies follow.—Ed.

Answer.—Reasonable caution would seem to suggest that a boy who has lost the vision of one eye should not play football. The resulting loss of peripheral vision and depth perception would be a considerable handicap and increase the probability of injury. The possibility of injury to and even loss of the other eye must also be given consideration. While a plastic face protector attaching to the headgear is now available, it provides no guarantee against eye injury. It affords some protection against blows, but small objects can penetrate the opening left to allow for clear vision. The final decision on the matter should be made by the parents in consultation with the physician only after carefully weighing of these factors against the boy's wish to participate. The modern outlook toward the handicapped is to encourage as near normal activity as possible, but there are other less hazardous sports to which such a youth could turn.

For boys with decreased vision in both eyes the problem differs. Even though a partially sighted player can compensate to some extent for his visual deficiency, he cannot be as safe or effective a performer in sports as he might be with normal vision. In sports like track, participants can wear their glasses. Some performers find it helpful to tape the bows at the temple to prevent displacement during play. In basketball satisfactory guards are available, but they are somewhat cumbersome and participants generally dislike wearing them. Since there is no guard that can make wearing glasses in football safe, the most satisfactory solution is contact lenses where these are practical and can be tolerated. The use of contact lenses by college and professional players is becoming commoner. For high school players, however, the cost is often prohibitive.

Answer.—Generally speaking it is foolhardy for a person with one eye to engage in contact sports. It is true that the possibility of injury or damage to the remaining eye are extremely remote, but with the possibility present, it is foolish

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

to expose oneself to the chance of total blindness. In persons in whom vision is less than normal without correction and in whom no organic ocular disease exists, there is no ocular contraindication to contact sports. A surprising number of outstanding football players have less than normal vision, usually because of simple myopia. When necessary, vision is brought to normal by use of contact lenses. For a person with a high degree of myopia with degenerative changes, contact sports would also be contraindicated because of the possibility of incurrence of retinal detachment.

GYMNASIUM FLOORS AND WALLS

To the Editor:—*In a gymnasium for adolescent boys, are there any increased hazards with a concrete rather than a wooden floor? In the same type of gymnasium, is there an increase in risk of serious accidents with a cinder block as opposed to a wooden wall?*

Herbert Notkin, M.D., Baltimore, Md.

Answer.—Concrete floors in gymnasiums (certainly extremely uncommon) would create a greater accident hazard than the usual hardwood floors as well as providing a less desirable playing surface. Comparative statistics on the incidence of accidents on concrete and wooden gymnasium floors do not seem to be available, probably because concrete has been used little if at all for this purpose.

Asphalt tile laid over concrete is now being utilized in some elementary school gymnasiums (playrooms). Because of their greater resiliency, hardwood floors for gymnasiums in secondary schools, colleges, and community centers used by older groups are considered much superior. Greatest objection to the asphalt tile floor laid over concrete has been the fatigue players feel is generated by the hard unyielding surface.

For elementary school playrooms (usually a miltipurpose room) the asphalt tile floor is coming into commoner use because of its less costly construction. Since physical education and athletic activities at this level are of shorter duration, less strenuous, and not so highly competitive as for older groups, the fatigue factor is considered less important.

Relative to cinder block versus other construction for gymnasium walls, there is no reason why this should create special hazards. Safety in relation to walls depends on two primary factors, (*a*) location of border lines of playing areas such as basketball and volleyball courts far enough away from walls to eliminate the possibility of running or falling into walls during play and (*b*) provision of close supervision directed toward confining activities that might involve violent contact with walls and resulting accidents to safe areas. As an additional precaution, protective padding such as gymnasium mats, fastened to the wall where special hazards may exist, for example, on walls beyond the goals of basketball courts, is essential accident insurance.

HOSPITAL COMMUNICATION SYSTEMS

To the Editor:—*I should like advice as to the public address or call system in a small county hospital with 45 beds. About 15 physicians are active members of the staff. Is a call system advised by the best administrators? If needed, what system is most satisfactory, a voice, bell, or light system? We now have a box where physicians in the hospital can check in and out by turning a switch. This informs the desk of their presence, but there is still considerable expenditure of effort and time on the part of the desk and nurses on the floor, finding not only physicians but janitors and supervisors when calls come in.*

M.D., Indiana.

Answer.—Communication is one of the normal problems to be solved in any hospital, large or small. Some type of call system is necessary for convenience and efficiency. This much is established by the comment. Further, a call system can be of vital importance in emergency situations. There is no one best system. There are advantages or disadvantages, with corresponding applications for each. A voice system is perhaps the most flexible and generally applicable. In operation it can be disturbing or annoying if speakers are badly located or not well modulated. On the nursing units, one should not expect the person being called to hear the call while attending a patient. The head nurse or whoever is attending the nursing station should know whether the person being called is at her unit and should assist in completing the contact. An advantage of this system is that it can be used in calling anyone who must be reached at locations about the premises. Calls can be made by code designation for fire emergency, fire drills, and autopsies without alarming patients. If bells or chimes are used, they would most likely be used for specific purposes in conjunction with a paging system. The light system is well adapted to the smaller hospital, since the illuminated call panel is then not too complex. The system depends on your staff's being observant and attentive. Its advantage is that it is quiet. It is less effective for general paging and is applicable, in particular, to medical and supervisory staff in areas where they will be watching for calls. There has been much discussion about individual pocket radio call systems. At present there are two systems of this type under development and test. It is not possible to make a valid appraisal at this time, as there is little use experience to date. This system holds much promise if some of the problems can be overcome.

DEATH IN A SILO

To the Editor:—*A man, aged 19, was found in a silo that had been filled with new silage 24 hours before. He was dead on my arrival. The silage, which consisted of shredded corn stalks, was not level; in fact, there was a definite sloping of silage, and the man was lying at the lowest part of the silage. What sort of gas is most likely to have caused this death?* *John E. Schroeppel, M.D., Winthrop, Minn.*

Answer.—The reactions involved in the production of silage involve as a first step atmospheric oxidation of the carbohydrate material present. The oxygen in a properly constructed and properly filled silo is rapidly consumed. This is then followed by a fermentation reaction usually through the activity of lactic-acid-forming bacteria. During the course of both types of reactions one of the end products is carbon dioxide gas, which accumulates in the confines of the silo. The high concentration of carbon dioxide gas and absence of oxygen may account for this death.

SKIN RESISTANCE

To the Editor:—*1. What is the least and the greatest amount of skin resistance encountered in the making of electrocardiograms? 2. Is skin resistance ever high enough to diminish the deflection amplitude? What is done to obtain the correct amplitude if this condition exists? 3. Does skin resistance vary with the thickness and nature of the underlying tissues? 4. Does skin resistance vary with skin color? 5. What is the difference between skin resistance of dry and that of moist skin?*

Samuel Waldman, M.D., Brooklyn, N. Y.

Answer.—Skin resistance is an important factor influencing the size of electrocardiographic deflections when a string galvanometer is used for measuring electric flow. The amplitude of deflections is, however, almost independent of skin resistance in commercial amplifying systems working with a high input resistance. The total skin resistance in arm to arm leads, using sodium chloride without preparation of the skin, may be as low as 2,000 to 16,000 ohms but usually amounts to 24,000 to 100,000 ohms per square centimeter of skin surface. It is least in the cubital fossa and especially in the palms. It is diminished after exercise, heat application, or in hyperthyroidism. It rises (as high as 1,400,000 ohms) during sleep, in myxedema, or after section of sympathetic nerves. It is not significantly changed by drying of the skin. Thus, skin resistance appears to have an inverse relationship to the amount of secretion of sweat that short circuits the high resistance of the horny layer of the skin. The color and content of pigment of the skin does not alter its resistance to electric flow. Considerable increase of the amplitude of deflections lowered by high skin resistance can be achieved by repeated and vigorous rubbing of the skin with special pastes and electrocardiographic jellies containing abrasive particles, which loosen the horny cells, saturate them with electrolytes, and force electrolytes into the sweat ducts.

HEADACHE IN DIABETIC AFTER EATING FATS

To the Editor:—*A white man, 40, a severe diabetic, has severe headaches after ingestion of any kind of fat. He had a thyroid operation about 18 years ago. I should like information concerning the handling of this idiosyncrasy. With a diabetic diet, he has difficulty getting enough to eat without taking some fat.* *W. G. Elliott, M.D., Cuthbert, Ga.*

Answer.—This kind of response to the ingestion of fat is certainly unusual. It should be tested under controlled conditions before any drastic changes in diet are made. If it is actually true that all fats produce headaches in this patient, one would be justified in giving a high carbohydrate diet (between 200 and 300 gm. a day) together with liberal amounts of protein, up to 125 gm. a day. The protein should consist of fat-poor foods, among the best of which are lean meat, milk (skimmed, if necessary) and ordinary bread. This diet alone would provide about 1,800 calories. The remaining caloric requirement might be made up by supplying vegetable instead of animal fat. The best sources of this are nuts, oleomargarine and the vegetable oils used in cooking and salad dressings.

AMAUROTIC IDIOCY

To the Editor:—*What is the possibility of recurrence of Tay-Sachs disease in a couple whose first-born was normal, whose second child has the condition, and who contemplates a third? What is the possibility of recurrence if an artificial insemination is performed with a donor other than the father? Should the donor be non-Jewish?*

Leon Zussman, M.D., New York.

Answer.—Tay-Sachs disease, known also by the terms amaurosis and amaurotic idiocy, has a tendency to recur in brothers and sisters. In 92 families in which the infantile form appeared, 135 infants suffered from the disease among a total of 456 brothers and sisters. One infant only was affected in 65 families; two had the disease in 17 families; three infants were affected in 6 families; four had the disease in 3 families. One family had six affected children.

Little is known regarding the relative importance of the sperm and the egg in the transmission of human traits. It is not known whether the egg or the sperm is primarily responsible for the transmission of Tay-Sachs disease. The condition appears more frequently in the Jewish race than in other races; therefore, the insemination of a Jewish woman with the sperm of a non-Jewish person should lessen the chance that an offspring conceived by the use of such sperm would have the disease. Such an insemination, however, would be no guarantee that her offspring would not be affected.

EXTRASYSTOLES

To the Editor:—*In Queries and Minor Notes in* The Journal, *Aug. 8, 1953, page 1494, dealing with extrasystoles, you had two consultants report on suppression. It was a surprise to me that neither one mentioned a simple and usually efficacious method. Full digitalization will usually suppress a majority of extrasystoles (or ventricular premature systoles) when there is no underlying myocardial disease. This treatment on a maintenance dosage basis has the added advantage that only one dose of digitalis is necessary per day.*

LEFT-HANDEDNESS

To the Editor:—*In connection with the subject of left-handedness discussed in Queries and Minor Notes of Aug. 15, 1953, may I draw attention to your tendency to repeat old misconceptions regarding handedness. The respondent may refer to my monograph on this subject, "The Master Hand," published by the American Orthopsychiatric Association in 1946, and to many other recent authorities who take a different view. I find that handedness is a culturally acquired trait, not a heredity one, and that right-handedness should be actively encouraged for better adjustment to our right-sided world. In response to the question, my opinion is that personality conflict and inhibitions are one of the original causes, not the effect, of left-handedness as well as of language disabilities in speech and reading. If improperly handled, left-handedness will increase the personality difficulties of a child. But more significant than the handedness is the basic personality problem of which it is merely a symptom. Psychological investigations into the child's general care may then be indicated. It is preferable to take reasonable steps early to discourage left-handedness in a patient, tolerant, and kindly fashion, and, contrary to many current opinions, no ill effects will ensue. If use of the left hand is allowed to continue, the child needs special attention in writing instruction; the paper needs to be inclined in a direction opposite to that of the right-handed child. The left-handed child is also handicapped in learning to read because English has a rightward direction, and care must be exercised to overcome reversals.*

SKIN PIGMENTATION IN INTERMARRIAGE

To the Editor:—*In Queries and Minor Notes in* The Journal, *Aug. 1, 1953, there is a question on the possibility of a child with negroid skin coloring being born to a couple phenotypically white but of part Negro ancestry. The opinion of your consultant is not shared by all students of human genetics, although it is popularly believed to be true and is often given as an argument against Negro-white miscegenation. In Kurt Stern's book "Principles of Human Genetics" (San Francisco, W. H. Freeman and Co., 1949, pp. 325-332), the genetics of pigmentary differences between the white and Negro races are discussed. It is stated that a marriage between a white segregant and a pure white person or between two white segregants should not, on theoretical grounds, give rise to darkly pigmented children, and that this expectation seems in fact to be fulfilled. He does not deny that children somewhat darker than their parents may be produced, but considers it highly unlikely that "black" or even very dark children will be found among the offspring of such unions. No well-authenticated instances had been reported prior to the publication of his book (1949), and the cases reported that proved accessible to investigation turned out to be based on hearsay rather than fact, or illegitimacy was involved.*

REMOVAL OF PERMANGANATE STAINS

To the Editor:—*A simpler, safer, and cheaper method for the removal of potassium permanganate stains from glass urethral syringes, porcelain, and intact skin, etc., is the use of a weak solution of oxalic acid. Any hardware store has oxalic acid. Handled correctly, it is far safer than the strong mineral acids suggested in Queries and Minor Notes, Sept. 19, 1953, page 258. Such strong mineral acids have no place in a physician's office because of their possible accidental dangers.*

Edward Palmer, M. D.
6639 Stanley Ave., Berwyn, Ill.

To the Editor:—*In Queries and Minor Notes, Sept. 19, 1953, page 258, Dr. C. H. Codelle of New York asks for stain remover for permanganate of potash. Oxalic acid is much milder than the ones mentioned, and a solution of it will remove such stains from utensils or the skin without damage. A pinch of crystals should be placed in a glass or small vessel full of water, and instruments soaked in it. In case of stains on the hands, some crystals can be taken in one hand, wet slightly, and rubbed on stained areas.*

PRESENT-DAY MEDICAL MANAGEMENT OF ALCOHOLISM

Daniel J. Feldman, M.D.
and
Howard D. Zucker, M.D., New York

In recent years there has been an increasing awareness by physicians, social scientists, and laymen that alcoholism is a medical problem and that it is a vast one. Several million persons in the United States alone are subject to this syndrome. With the introduction of new drugs and the advance of psychiatric knowledge and techniques and with the advent of Alcoholics Anonymous, the former gloomy prognosis of alcoholism has been replaced by an attitude of hopefulness and interest that is entirely justified. A variety of excellent papers on specialized aspects of alcoholism have appeared in recent years, but, as is often the case, the literature leaves the physician who deals with alcoholics only occasionally in the difficult position of having to make his own synthesis from these various sources. It is our aim to fill this gap by discussing the day-to day medical management of alcoholism.

It must be emphasized that we have arbitrarily excluded consideration of psychotherapy from this presentation. This is not a value judgment. We are of the opinion that most alcoholics have underlying personality problems of varying magnitude and that proper treatment must include a therapeutic approach to these problems through one or more of many fruitful channels, such as counseling by an understanding physician or religious advisor, individual or group psychotherapy, or Alcoholics Anonymous. Such a systematic approach to reorientation of the personality is fundamental in the long-term treatment of alcoholism.

When alcoholic patients are first seen, they may present themselves in the acute alcoholic state, the postalcoholic state, or in the chronic state, hoping to avoid further flare-ups. Each of these conditions presents special probems in management, and each will be treated separately.

ACUTE ALCOHOLIC STATE

The acute alcoholic state may be defined as a period of uncontrolled drinking that interferes with a person's ability to function effectively. It may last from a day or two to several months, and it is usually accompanied by varying degrees of acute alcoholic intoxication. The duration is often determined only by the patient's ability to continue to drink, and this may vary widely in different persons. This phase is what most laymen consider the characteristic behavior of the alcoholic. It is what they refer to as a "spree," "binge," or "bender." Much severe and irreparable harm may be done to family relationships and to job and other interpersonal associations during an acute alcoholic episode. The bodily harm, accidents, and difficulty with the law that so often occur in the course of alcoholism are most frequently encountered during this phase of the illness.

When successfully managed, this phase of alcoholic disease offers an excellent opportunity for orientation of the patient to the real nature of his illness and to begin the over-all, long-range program necessary for its alleviation and the patient's rehabilitation. To look upon therapy administered during this phase as a simple "drying out procedure" is a mistake, and, if the only concern of the physician is to sober the patient up, he will miss an important opportunity to really help the alcoholic toward a useful, productive life.

It is held by many that it is useless to attempt to treat anyone during the acute alcoholic state unless the phase has run its course and the patient himself is anxious for treatment. This may be generally true, but not infrequently the physican may be able to convince a patient to accept treatment despite considerable reservation on the patient's part. If the therapy administered can successfully break the circle and ease the difficult immediate postalcoholic period, as many of the newer methods can, then much unnecessary suffering is eliminated and the possibility of a serious tragedy may be avoided. We do not question the advantage of wholehearted cooperation by the patient; experience shows that, if he can be prevailed on to try treatment, the acute alcoholic episode may be considerably shortened. While trying to talk the acutely alcoholic patient into accepting therapy is worth while, it must be remembered that threats and an attitude of disapproval will do more harm than good and that waiting may prove necessary.

The ideal place for treatment of the acutely alcoholic patient is the hospital, and every effort should be made

---

This paper is a combination of two papers read as part of a symposium of the New York City Medical Committee on Alcoholism, April 15, 1953.

to convince both the patient and the hospital of the wisdom of this arrangement. It is surprising how little difficulty most acutely alcoholic patients cause in hospitals, a fact repeatedly confirmed by those hospitals courageous enough to admit this type of patient on the same basis as any other. It seems as though merely treating these people as any other sick person somehow makes them more tractable and cooperative. Occasionally, they become model patients. Hospitalization in open or general hospitals is not to be recommended if the patient is actively against any treatment or if force must be used. It is also best to treat active delirium tremens under more protected conditions than are generally available in open hospitals, although this can also be accomplished when necessary.

Hospitalization allows the physician complete control over the patient and is particularly helpful in the abrupt withdrawal of alcohol, a condition we believe preferable in the management of the acute alcoholic state. It removes the patient from members of his family and from home situations that may have been instrumental in bringing on the acute drinking episode and that are, indeed, an important factor in chronic alcoholism. Many of the newer techniques to be described are best carried out in the hospital where adequate laboratory and other special facilities are readily available.

Although we feel that hospitalization in acute alcoholism affords the most efficient way to therapy, such patients can be treated at home and even on an ambulatory basis. A great deal depends on the severity of the acute phase, the nature of the home, and the facilities available therein, and it goes without saying that a great deal depends on the motivation and sincerity of the patient. The use of nurses for the first few days may greatly simplify the patient's care.

A complete physical evaluation should be performed as soon as is practical. Concomitant chronic or acute illness is not uncommon in the alcoholic and may complicate the acute alcoholic phase, or vice versa. It is easily overlooked in the turmoil accompanying acute alcoholism. Knowledge of other illness is important in determining the choice of therapies, particularly if hormonal treatment is contemplated.

The specific management of the acute alcoholic state may be conveniently considered in three general areas.

Correction of Existing Physical and Physiological Abnormalities.—Correction of existing abnormalities should include consideration of fluid balance, correction of salt and nutritional deficiences when they exist, and diagnosis and correction of existing diseases. Most patients who have been drinking in an uncontrolled fashion for any length of time have sustained some degree of dehydration; this state should be recognized and corrected. In mild cases in which the patient is cooperative, the oral administration of whatever fluids the patient prefers is sufficient. A number of physicians feel that a varying but significant and specific loss of sodium chloride accompanies any acute alcoholic episode. This salt depletion is, in the opinion of some, a major factor in the patient's continuing compulsive drinking. In view of the foregoing and in view of recent concepts that implicate adrenal hypofunction in the acute alcoholic state, the use of salt in the treatment of this condition has been made a routine procedure by many. The value of salt has been clearly borne out in our experience. When possible, a patient may take it by mouth, either by taking salt tablets or by salting ingested fluids heavily. The intravenous use of isotonic sodium chloride solution is, of course, always available. Two to four grams of sodium chloride is the usual dose in the first 24 hours, of which not more than 2 gm. should be given intravenously.

The use of vitamins, particularly the B group and vitamin C, has been met with varying amounts of enthusiasm from time to time. By and large, we feel that their use in the treatment of the acute alcoholic state is warranted, since all other foods are often abandoned for alcohol and since a certain degree of acute avitaminosis can be presumed present after a drinking bout of more than a few days. In addition, the effect of vitamins of the B group on the state of the liver, and of C on the adrenal gland, is a beneficial one. Vitamins can be administered orally or intravenously. Large doses of vitamin B and at least 0.5 to 1 gm. of vitamin C should be given daily for the first two or three days.

Management of Symptoms Associated with Acute Alcoholic Intoxication.—Symptoms, such as marked hyperexcitability, restlessness, and nausea or vomiting, may be features of acute intoxication, and their control is a very important part of the management of the patient. As part of this management, one should also consider the use of agents to hasten the body metabolism of alcohol. Although considerable doubt exists as to whether it is possible to speed the metabolism of alcohol in the body, certain persons respond to intravenous administration of dextrose or dextrose and insulin. Inasmuch as the intravenous use of dextrose may be considered generally beneficial in the treatment of the acute alcoholic state, its use, particularly when severe intoxication is present, is advised. There is as yet no clear-cut evidence to support the idea that the use of insulin hastens the metabolism of alcohol in the body.

The management of acute alcoholic intoxication has been radically changed by the introduction of the adrenal steroid hormones. We feel this represents a significant advance. Although the exact relationship of adrenal function to alcoholism has by no means been conclusively demonstrated, it is evident that the use of these steroids in the acute alcoholic patient may result in striking and rapid improvement. Our experience has been mainly in the use of aqueous extracts of the adrenal gland and the pituitary-adrenal-cortical-stimulating hormone (ACTH). The use of these substances intravenously in those patients requiring more than merely mild symptomatic therapy has resulted in rapid relief of the acute intoxication, marked diminution in the symptoms usually associated with the immediate postalcoholic state, and a shorter period of duration of these symptoms. In many instances, it has made the need for sedation much less urgent and has frequently made only small amounts of sedatives necessary. We have used these hormones as soon as treatment was instituted. When aqueous cortical extracts are to be used, 20 to 60 cc. should be added to 1,000 cc. of dextrose and sodium chloride solution infusion, and the infusion should be administered at the usual rate. Twenty-five milligrams of corticotropin (ACTH) in a similar infusion may be administered. Such an infusion should take from six to eight hours to administer and may be repeated daily for a few days. Although significant side-effects are not likely on this small dosage, it is wiser not to exceed 2 gm. of sodium chloride per day. If significant cardiac or renal disease is present, the use of aqueous extracts probably widens the margin of safety. In patients in the acute alcoholic state, we have seen no ill-effects from the use of the adrenal steroids in the amounts described.

The relationship of adrenal steroid therapy and acute psychotic episodes is well established. When there is reason to suspect an underlying psychotic or prepsychotic personality, it is wiser to lessen the danger, to use the adrenal aqueous extracts than corticotropin. Although the use of adrenal steroids diminishes the need for sedation in the acute alcoholic state, some sedation is usually needed. Whenever possible, it is best to avoid the use of barbiturates because of the increased danger of establishing addiction in the alcoholic patient. Trichloroacetaldehyde (Chloral) or bromide and trichloroacetaldehyde have been useful in those patients receiving steroid therapy. The danger of giving trichloroacetaldehyde to an acutely intoxicated patient must be borne in mind, however. The relatively rare occurrence of trichloracetaldehyde intoxication should be watched for. Paraldehyde in small doses still is an extremely useful sedative in the alcoholic. In general, the fewer sedatives used the better, and the avoidance of the barbiturates when possible is a good policy. When barbiturates cannot be avoided, they should be reserved for giving a good night's rest.

Control of Symptoms Associated with the Immediate Postalcoholic State.—Marked tremor and tension feelings and other symptoms generally grouped together as psychomotor hyperactivity may be a significant feature of the immediate postalcoholic state. These symptoms are very disturbing to the patient and are the most important cause of immediate resumption of drinking. It is of the utmost importance that every effort be made to relieve them and that the patient be kept under strict control until such symptoms have sufficiently disappeared to make the likelihood of resumption of drinking minimal.

As has been previously mentioned, the number and degree of immediate postalcoholic symptoms is markedly lessened, if not altogether obviated, by the use of the adrenal steroids. If such symptoms are significant, the use of mephenesin (Tolserol) in doses of 0.5 to 1.5 gm. every four to six hours may be helpful. It is during this phase of the illness that addiction to sedatives is most likely to occur. Sedatives should be used if necessary but in a very controlled manner. The prescriptions issued to the patient should be for minimal amounts and repeated, rather than for larger amounts. When postalcoholic nausea and vomiting is a significant feature, the use of Apolamine (phenobarbital, 15 mg.; atropin sulfate, 0.1 mg.; scopolamine hydrobromide, 0.2 mg.; benzocaine, 0.1 gm.; riboflavin, 4 mg.; pyridoxine, 2.5 mg.; and nicotinamide, 2.5 mg.), useful in the control of these symptoms, may alleviate the condition when general measures have not been successful.

Depression and guilt feelings are often a prominent part of the postalcoholic state. Simple (not effusive) reassurance and gentle planning for the future (without encouraging or permitting unreasonable promises) can help relieve these symptoms.

Delirium tremens is a special complication of the postalcoholic state that is extremely important to recognize and deal with. It may result in death if unrecognized or mismanaged. Essentially, it is characterized by acute psychomotor agitation, acute visual and auditory hallucinations, tachycardia, and, ultimately, signs of peripheral circulatory collapse. The use of the adrenal steroids in delirium tremens has resulted in a really significant advance in the management of this condition and, not frequently, has been lifesaving. The method of their use is the same as described in the general use of the adrenal steroids in acute alcoholism. If aqueous adrenal extract is used, large quantities should be used (at least 40 to 60 cc. per 1,000 cc. infusion). Corticotropin, given intravenously in doses of 25 to 50 mg. per day, seems to be adequate. The use of supportive therapy, including additional fluid, salt, vitamins, and sedation, must be used as the indication arises. It is interesting to speculate as to how often the development of delirium tremens may have been avoided by the early use of adrenal steroid therapy in acute alcoholism.

Alcoholic coma is a special complication of the acute alcoholic state. The coma is, of course, due to the anesthetic effect of the alcohol on the brain, and the treatment is much the same as that of any anesthetic coma. The importance of watching for evidence of respiratory failure must be stressed. The possibility of pulmonary infections complicating prolonged coma should be borne in mind. Proper nursing care and the use of antibiotics are part of the management.

Convulsions occasionally are a feature of the postalcoholic state. When they occur, they usually appear after the acute drinking has stopped and, therefore, might be considered a complication of the immediate postalcoholic period. They can be quite severe. In most instances, no evidence of true epilepsy can be found. When this complication does occur, however, a thorough study including electroencephalography should be done if it has not been done in the past. Adequate dosage of anticonvulsive drugs should be used to control the episodes. These convulsions are usually limited to the immediate postalcoholic period, and, when they do occur, they tend to reappear with each alcoholic episode.

LONG-RANGE MEDICAL THERAPY

The management of the alcoholic between bouts has stirred up the hopes and anxieties of alcoholics, their families, and their physicians for many centuries. As is often true of complicated problems, simple panaceas are constantly sought and oft proclaimed. There is not now, and probably never will be, any simple method of turning an alcoholic into a nonalcoholic; as in any chronic illness, a period of long hard work must be contemplated.

Williams[1] and Mardones[2] advocate an elaborate nutritional regimen including massive vitamin therapy as a cure for alcoholism. They postulate that alcoholism is a metabolic disease of hereditary nature. Although most patients on such a schedule experience some feelings of well-being, various workers, following those techniques rigidly, have seen no significant effects on the drinking patterns of most alcoholics. Others claim mediocre results. The lack of clear-cut results does not seem surprising. Many alcoholics can voluntarily stop drinking for varying lengths of time, from weeks to months, for reasons that they consider adequate. For instance, an internist recently told of her surprise at the good health of two of her alcoholic patients. Each one when questioned said, "But of course, I've stopped drinking for Lent." "How could they do that," she asked, "if this were primarily a biochemical problem?"

J.; Berry, L. J., and Beerstecher, E., Jr.: Biochemical Individuality: Genetotrophic Factors in the Etiology of Alcoholism, Arch. Biochem. 23: 275-290, 1949. Williams, R. J.: Nutrition and Alcoholism, Norman, Okla., University of Oklahoma Press, 1951, pp. x-82; Alcoholism as a Nutritional Problem, J. Clin. Nutrition 1: 32-36, 1952.

[2] Mardones, J. R.: On the Relationship Between Deficiency of B Vitamins and Alcohol Intake in Rats, Quart. J. Stud. Alcohol. 12: 563-575, 1951.

Hormone treatment is a more complicated subject. As mentioned previously, there is evidence of adrenal depletion during alcoholic bouts. There is also a body of evidence that there may be adrenal depletion in chronic alcoholics. A number of reports have been published of patients who stopped drinking for considerable periods of time [3] while receiving injections of adrenal cortical extracts (ACE and Eschatin); these are given daily, at first, and then at weekly intervals. The doses have varied from 1 to 5 or 10 cc. given intravenously or intramuscularly. These are aqueous extracts; the lipoextract is never given intravenously. Corticotropin and cortisone have been used in such treatment regimens with similar results. Dosage schedules are somewhat lower than in many of the medical diseases in which they are effective. Here again the long-term results have not, in most hands, shown that any hormone is a sole and sufficient answer to the problems of most alcoholics, and, with one exception, none of the investigators have made such a claim. In this regard, the voluntary abstainers again illustrate a theoretical objection to a purely biochemical mechanism.

Neither vitamins nor hormones are the cure for chronic alcoholism, but this does not mean that vitamins, hormones, and dietotherapy have no place in its treatment. On the contrary, their role is important. Approximately 25% of the patients starting treatment for chronic alcoholism show evidence of moderate or severe malnutrition—often with lip, hair, and skin changes associated with depletion. The sense of physical well-being resulting from replacement of vitamins, proteins, and hormones and the sense of emotional ease resulting from the direct evidence of the interest of a competent physician both play an important role in helping these patients stay on the difficult road of sobriety and learn about themselves and their disease. Some physicians feel that, aside from the question of malnutrition, a low carbohydrate diet is important in alcoholics. Our own experience has not convinced us of this.

Conditioned reflex therapy is just what its name implies; it is a method of establishing an aversion to alcohol by the repeated association of nausea and sickness with the drinking of alcoholic beverages. This method has been used extensively on the west coast [4] and to a lesser degree in Boston, but it has not obtained a significant foothold elsewhere in this country. Doubtless, this treatment helps some alcoholics. Enough patients have been seen who had relapses following this training to make us feel that at present it is not the method of choice. From a theoretical point of view, the ultimate failure in some cases is not surprising, for the patients are offered no positive incentives to stop their drinking and no new outlets for the forces that led them to drink abnormally.

DISULFIRAM-ALCOHOL REACTION

We feel that the most important advance in the medical management of chronic alcoholism has been the advent of disulfiram (Antabuse). The role of disulfiram is to provide the patient with a simple and clear-cut temporary reason not to drink, namely the inability to drink without getting sick. This reality ordinarily outweighs any rationalizations or impulses of the moment. Psychiatric data have made clear the ambivalence in the alcoholic's attitudes toward drinking. When he seeks help, the dominant part of him wants to stop drinking, but there are parts of him that dissent boldly from that decision. This is the reason disulfiram has proved so helpful; the reality of the disulfiram-alcohol reaction helps many patients avoid that first drink and provides a built-in cooling off period during which they cannot run blindly and self-destructively away from their fears and troubles.

A young woman who had had several years of psychotherapy commented on this recently. "My psychotherapy has helped me in every way except with the drinking," she said. "Antabuse has been a godsend. I still get in rages against my husband and against my psychiatrist, and, always before, when I was angry like that, I would get drunk. Now I can't, and by the time I can, if I stop the pills, I'm not angry any more and so I start the pills again."

What of the effectiveness of disulfiram? It is surprising, considering all the variability and variables involved, that the statistics in recent papers on disulfiram therapy turn out very much the same. Larimer [5] was able to keep in touch with 118 of 193 patients. Of the 118, 25, 21%, seemed to be total failures in that they abandoned disulfiram and reverted to their previous drinking habits. Forty per cent of the patients seemed to conquer their alcoholism with the aid of disulfiram; that is, they stayed sober and continued to take disulfiram. Another 25% stayed sober or had one or two minor relapses after having taken disulfiram for a variable period of time. The final 16% had taken disulfiram intermittently and had done some drinking. Those who have had experience with alcoholism will agree that some of the 78% who seem to have been more or less rehabilitated by disulfiram will later seem to be failures, but it is also true that some of the so-called absolute failures will later return for further help and may eventually be rehabilitated. Whatever percentage of cure one accepts, out of the 78%, it is likely to be much higher than most students of the field would have thought possible in other days.

5. Larimer, R. C.: Treatment of Alcoholism with Antabuse®, J. A. M. A. **150**: 79-83 (Sept. 13) 1952.

Mann and his group in Hartford [6] reported a smaller series intensively studied. Of their 32 patients, 7, or 22%, were so-called absolute failures—1% more than in Larimer's series. If their figures are studied, it will be seen that the remaining 78% either were helped in varying degree or were in a condition to be helped, since administration of the drug in 25% of the patients was stopped by their physicians for reasons that at present might not be considered obligatory. Statistical and personal experience both show that disulfiram puts many alcoholics in a position to be rehabilitated. What then about the practical points of pharmacology, dosage and toxicity, and indications and contraindications?

The consensus is that a single 0.5 gm. tablet daily for an indefinite period of time is a satisfactory dose. Certainly the larger doses given in the early days of disulfiram therapy had many ill-effects and are not to be recommended. A considerable number of patients will complain persistently of side-effects that will be described later; these patients may be carried on 0.25 gm. (one-third of a tablet) daily with adequate protection, which means sufficient reactivity to alcohol. A few patients can be maintained on 0.125 gm. (one-quarter of a tablet), rarely on less.

Since there is no cumulative effect of the drug, no intermissions are indicated. On discontinuing therapy, it usually takes from 48 to 72 hours to clear the blood sufficiently to permit drinking without toxic effects. In some cases, the effects persist for five to seven days. An honest discussion of this variable with the patient is, we feel, necessary. A patient who has been told that the drug effect lasts five days and who finds that it lasts only two or three days will feel that he has been fooled; most alcoholics cannot tolerate this feeling.

The method of administration is psychologically important. The tablets should never be administered surreptitiously, although families often make that suggestion. Unless the patient knows that he has disulfiram in his system, he has no protection; he is merely in a position to be poisoned or to unknowingly poison himself. The patient is the one who must stop drinking, and he should take the pill without prying or checking on the part of the family. Lies, evasions, and subterfuges are part of the alcoholic syndrome, and these old destructive habits will be brought into play if snooping is encouraged. Only the physician who has the courage to understand and not to judge the patient for lapses is in a position to help the patient get used to the drug and to abstaining.

We often advise our patients to take their tablet in the morning when they brush their teeth, in an effort to make taking the pill as habitual and free from doubt and unconscious evasions as possible. As soon as the tablet has to be thought about, it is likely to be omitted. For the occasional patient who remains persistently drowsy on disulfiram, the tablet can be taken at night so it will act as a welcome sedative but still give adequate protection for the following day.

In addition to working out a dosage schedule, it is important to warn the patient against alcohol contained in substances not usually associated with drinking. Many medicines have alcoholic vehicles. These cannot be used and should be specifically warned against. Wine cookery, wine sauces, and wine vinegars can prove toxic, as can alcohol fumes in large volume.

Many side-effects have been reported. In our experience, drowsiness, headache, nausea, loss of appetite, and fatiguability are most commonly seen. Some patients are troubled by change of bowel habit with or without abdominal cramps, some by diminished potency, and a few by a metallic taste or a rash. Many patients report one or another symptom during the first days on disulfiram. If the symptom is not severe, simple reassurance usually suffices to calm the patient, and the symptom disappears spontaneously after a few days or weeks. If the symptom is severe or persistent, the dose should be diminished, as previously mentioned.

The sole serious toxicity of disulfiram, other than the disulfiram-alcohol reaction, is psychosis. There has been considerable confusion in the field, and this is reflected in the literature, as to whether the disulfiram psychoses have represented the precipitation of psychoses previously maintained in a latent form in a supersaturated alcohol solution. Probably both occur, but the drug psychosis seems to be the commoner mechanism. This is illustrated by the fact that in the early days of high disulfiram dosage psychotic episodes were seen in as many as 10% of cases [7]; since the dose has been reduced, these reactions are very rare. Experience also shows that patients who have had psychotic reactions while taking disulfiram usually revert to their previous emotional state within one to three weeks after they stop taking the drug, and many of these patients have been maintained for years on smaller doses of disulfiram without further psychotic breaks.[8] In those cases in which underlying psychosis is suspected, psychiatric consultation should be obtained before starting disulfiram therapy.

The disulfiram-alcohol reaction is a separate pharmacological entity. Clinically the reaction is characterized in its first stages by flushing, headache, nausea, salivation, burning of the eyes, and dyspnea; usually these occur 10 to 20 minutes after ingestion of alcohol. If severe, the reaction progresses to hypotension, vomiting, further dyspnea, pallor or cyanosis, and a feeling of tightness in the chest. Ultimately severe hypotension, extreme weakness, and collapse may ensue. Although the severity of the reaction generally parallels the amount of alcohol ingested, this is not always true. Occasionally, a small amount of alcohol precipitates a violet reaction. Untreated severe reactions may continue for four to eight hours.

The treatment of disulfiram-alcohol reactions is simple and effective. It consists of the administration of antihistamine drugs and the conventional treatment of shock. Antihistamines alone halt the symptoms of many reactions because of their specific blocking effect on the mechanisms producing the reaction; often the patient falls into a restful sleep, a sleep said by Martensen-Larsen [9] and others to be more certain and more restful than that obtained with conventional sedative measures.

[8] Fox, R.: Personal communication to the authors.

[9] Martensen-Larsen, O.: Personal communication to the authors.

The dosage of antihistamine used is the same as is used in other conditions. Intravenous administration of diphenhydramine (Benadryl) hydrochloride may be the treatment of choice if a very rapid effect is necessary. If shock supervenes during the reaction, the usual measures (fluids intravenously with added constrictor amines, oxygen, and the Trendelenburg position) should be used. Cardiac stimulants may be added. Intravenous administration of ascorbic acid and iron does not seem to have any great influence on severe reactions.

The question is often raised whether every patient who is going to take disulfiram should undergo a disulfiram-alcohol reaction? To our minds, the word "every" carries the answer to the question; no human problem can be answered so categorically. There are many alcoholics who have a "devil may care," "nothing can hurt me" attitude; these patients characteristically have a very bland medical history, often suspiciously bland. Such a person is ducking reality, and the reality of personal experience with a disulfiram-alcohol reaction is of great importance. On the other hand, there are certain alcoholics who are hypochondriacs; they are consciously terrified by every pain or ache or potential pain or ache that they encounter. There seems no need to impress such a frightened patient with the danger of drinking while taking disulfiram; in some, the threat of a test acts as a real barrier between the patient and treatment.

The question of submitting patients to a test reaction when they fall in neither of these extreme categories must be left to the judgment of the physician. In any case, test reactions are absolutely contraindicated in patients in whom there is coexistent coronary artery disease, significant hypertension, or other disease that might be aggravated by shock. Test reactions are best produced in the hospital where fluid, oxygen, and cardiac stimulants are easily available and where the magic of the hospital adds to the impression of the seriousness with which the physician views the reaction. The amount of alcohol that will produce a reaction varies with the patient; to us it seems prudent to try a small dose, such as a half an ounce of whisky or its equivalent, to be followed by an equal quantity in 20 minutes if there is no reaction.

CONTRAINDICATIONS TO DISULFIRAM

The matter of contraindications to disulfiram has been overinflated. There seem to be no absolute contraindications except a personality clearly on the borderline of overt psychosis. Since disulfiram is in part excreted through the bile, liver disease has been stated as a contraindication, but many cirrhotics have been treated without ill-effects. Diabetes mellitus has been said to be a contraindication, but, again, experience does not support this view; there may, however, be changes in insulin requirements. Coronary artery disease and severe hypertension, as mentioned, are contraindications to test reactions, but experience shows they are not contraindications to treatment in a person stable enough to be informed of the dangers of possible reactions. In weighting the advisability of using disulfiram in cases in which coexistent illness presents a possible danger, one must consider the seriousness of the alcoholic syndrome in that patient, its social and physical impacts and their destructiveness, and, always, the likelihood of progression.

Anxiety and its protean somatic manifestations are commonly seen in chronic alcoholics. The use of barbiturates and other addicting drugs in controlling these symptoms should be extremely cautious. Some patients get as drunk on barbiturates as they do on alcohol, and many are undoubtedly susceptible to drug addiction because of the similar psychological and physiological factors involved in most addictions. Mephenesin is a much safer drug to help lessen the feelings of tension of these patients; unfortunately, its practical usefulness is quite unpredictable. Mephenesin is very helpful for some patients and quite useless for others. This is a matter of trial and error at present. When used in 0.5 to 1.5 gm. doses, it is best taken with food. One of the important roles of the physician in the treatment of these symptoms of anxiety is reassurance. This may seem obvious, but it is fundamental in the treatment of alcoholics. Many of these persons are certain that their bodies have been irreparably damaged by drink, but this is seldom a reality in the middle or upper class alcoholic group. Other alcoholics become equally certain that abstinence is wreaking bodily injury; this is untrue, except for some untreated cases of delirium tremens. The physician who values only his scientific knowledge and not his ability to provide understanding and reassurance will have difficulty in helping alcoholic patients.

In the long run, anxiety and the other uncontrolled impulses and emotions must be dealt with through understanding and reeducation of the patient. Although the processes leading to such changes fall outside of the scope of this paper, they must not fall outside of the scope of the treatment. The physician should either undertake this reeducation or refer his patient to those who will undertake it.

SUMMARY AND CONCLUSIONS

Alcoholism is a medical problem with somatic and psychological aspects, both of which may be modified by modern treatment. There is no longer any reason for the hopeless attitude that formerly surrounded this affliction.

The acute alcoholic state is a crisis in the course of chronic alcoholism. The most destructive acts and consequences of the alcoholic's course usually occur in this phase. The acute alcoholic state presents physiological and psychological problems peculiar to it. Their nature and alleviation are discussed with respect to hospitalization, fluid and electrolyte balance, and sedation. In particular, the use of the adrenal steroids has made the management of this phase much easier and more successful.

The long-range treatment must include medical and psychological approaches. Recently developed medical therapies have greatly increased the physician's success in the management of alcoholism; these are discussed, including the use of nutritional substances, hormones, and disulfiram (Antabuse). Of these, disulfiram seems to be the most important development in the long-range medical treatment of alcoholism, and its use is described in detail. With the revision of dosage schedules, the number of disabling side-effects has been markedly reduced, and experience has shown that many previous contraindications no longer seem valid. The antihistamines appear to be a specific antidote for alcohol-disulfiram reaction, and severe, potentially dangerous reactions can now be controlled to a great degree.

Medical therapies can be successful only when administered by a physician who has a sympathetic understanding of the alcoholic in the broadest sense and who is willing to exercise great patience and tolerance in his approach to the alcoholic patient. By the same token, the psychotherapy of alcoholism can be carried out by a sympathetic physician; in many cases, psychiatric referral is not necessary. Community resources can play an important part in the patient's rehabilitation and should not be overlooked.

WHAT PHILADELPHIA PHYSICIANS TELL PATIENTS WITH CANCER

William T. Fitts Jr., M.D.
and
I. S. Ravdin, M.D., Philadelphia

The recent campaign to educate the American layman about cancer has undoubtedly made him "cancer conscious." The leaders of the campaign believe that at present the chief hope of reducing the high cancer death rate depends on treating the disease in its first stages. They have given wide publicity to the symptoms and signs of cancer to encourage the public to seek medical advice early, believing the advantages of early treatment outweigh the disadvantages of producing widespread cancerophobia. The information given to the layman is clear and specific, written by experts in the medical profession; there are pamphlets entitled "Cancer of the Breast," "Cancer of the Digestive Tract," "Cancer of the Rectum," and "What Everyone Should Know About Cancer." To a greater degree than ever before, the public is being taken into the confidence of the medical profession and is being asked to assist in the early diagnosis of a disease. Can we inform the layman up to a point and still keep him from recognizing a positive diagnosis?

The decision to tell or not to tell a patient he has cancer is largely an individual matter, varying with the personalities involved, and opinions vary as to the best policy. Some recent articles [1] have taken the view that all patients with cancer should be told the absolute truth. Studies of lay-attitude toward the problem have indicated that many laymen feel strongly that they themselves would want to be told. It has been our impression that most physicians in the Philadelphia area do not tell patients they have cancer, and we thought it worth while to determine the attitudes of physicians in a given locality. We have attempted to determine the opinions of the physicians of Philadelphia County by means of a written questionnaire.

THE QUESTIONNAIRE

Because we believed that too great a burden would be placed on the busy physician if we asked him for an exact breakdown of the number of patients he had or had not told in a specified time, we made up a questionnaire requiring one of four general answers: 1. I always tell the patient he has cancer. 2. I never tell the patient he has cancer. 3. I usually tell the patient he has cancer but do not under certain circumstances. 4. I usually do not tell the patient he has cancer but do tell under certain circumstances.

COMPOSITION OF SAMPLE

We selected eight groups of physicians in the Philadelphia area who, because of the type of medicine they practice, might be expected to offer suggestions on the management of cancer patients (table 1). Five of these (radiologists, dermatologists, surgeons, gynecologists, and internists) are specialists who come in frequent contact with cancer patients. A sixth group, the psychiatrists, see fewer patients with cancer than the above-mentioned specialty groups but were selected because they study the mental and emotional reactions to organic disease and might offer valuable opinions. A seventh group, members of the Academy of General Practice, were selected to represent the family physician, who is chiefly responsible for deciding what the patient is to be told and who is best qualified to evaluate the effect on the patient of telling him of his cancer. To check the specialty groups (including the members of the Academy of General Practice) against a nonspecialty group, a large number of physicians who were listed as having no specialty and who were not members of the Academy of General Practice were included in a nonspecialty group.

Subject to the definitions given above, the total number of Philadelphia physicians falling into the 8 groups was 2,400, as shown in table 1. This number constituted the universe from which our sample was drawn. This number does not represent all of the physicians in Philadelphia County, however, since several of the specialties were not included in the study and specialists who were not listed in the Directory of Medical Specialists were not included.

The questionnaires were mailed to 444 physicians, or almost 20% of the 2,400 physicians under consideration. This sample of 444 was selected serially from alphabetical listings of the several specialties after nonresidents had been excluded. The sampling ratios are shown in table 1. Approximately a third of most of these groups

Prof. Dorothy S. Thomas and Dr. Everett Lee of the Department of Sociology, University of Pennsylvania, assisted with the sampling methods and the preparation of the questionnaire.

1. Kelly, W. D., and Friesen, S. R.: Do Cancer Patients Want to Be Told? Surgery 27: 822, 1950. Wangensteen, O. H.: Should Patients Be Told They Have Cancer? ibid. 27: 944, 1950.

were questioned. The dermatology-syphilology group was so small, however, that questionnaires were sent to half of the group. On the other hand, so many fell into the nonspecialty category that only 10% of the group were sampled.

RESPONSE TO QUESTIONNAIRE

The excellent cooperation of the physicians in answering the questionnaire was gratifying. Eighty-nine per cent of the questionnaires were returned with some answer, and 82% of the questionnaires had answers complete enough to be analyzed. Seven per cent could not be analyzed for one of the following reasons: 1. The physician was out of practice. 2. The physician had no cancer patients. 3. The answer given could not be fitted into one of our four types of response. No one of the eight groups lacked representation, since in all instances a large percentage of each group returned the questionnaire.

TABLE 1.—*Composition of Sample of Philadelphia Physicians by Type of Practice* *

	Total No. of Physicians in Group	Physicians Sent Questionnaire	
		No.	%
Radiology	101	33	33
Dermatology-Syphilology	39	20	51
Internal Medicine	226	72	32
Surgery	127	42	33
Psychiatry-Neurology	130	43	33
Obstetrics-Gynecology	124	42	34
Academy of General Practice	119	40	33
Nonspecialty group	1,534	152	10
Total	2,400	444	19

* Specialists are those listed by the Directory of Medical Specialists, vol. 5, 1951; the list for the members of the Academy of General Practice was compiled by the secretary of that organization in Philadelphia; the nonspecialty group was obtained from the Medical Directory of Philadelphia and Metropolitan Area, October, 1951.

ANALYSIS OF ANSWERS TO QUESTIONNAIRE

Table 2 summarizes the answers to the four basic questions and shows conclusively that Philadelphia physicians in general do not tell patients they have cancer.

TABLE 2.—*What Philadelphia Physicians Tell Cancer Patients**

	Percentage of Total Answers
Always tell patient	3
Usually tell patient	28
Usually do not tell patient	57
Never tell patient	12
	100

* The sampling ratio varied from 10% to 51% for the nonspecialty group and the dermatologists respectively (table 1). If answers were weighted according to the proportions in the sample, the averages shown above would be as follows: Always tell patient, 3%; usually tell patient, 30%; usually do not tell patient, 55%; and never tell patient, 12%.

Only 3% stated that they always tell, and only 28% stated that they usually tell. Approximately 70% either never tell or usually do not tell. If the answers are weighted according to the proportions of each specialty in the sample, the percentages in table 2 would not be changed by any considerable degree; as can be seen from the footnote in table 2, weighting does not create a discrepancy of more than 2%.

Table 3 offers an analysis of what patients are told according to specialty groups. In this table the physicians have been combined into two general groups: (1) those who always or usually tell and (2) those who never or usually do not tell. The most striking feature is the response of the dermatologists, 94% of whom tend to tell the patient he has cancer. This difference in practice is almost certainly due to the fact that the dermatologists treat cancer with an unusually favorable prognosis and their patients can be cured in the majority of instances. This opinion was confirmed by several of the dermatologists who appended comments to their questionnaires. For example, one dermatologist stated: "Since cutaneous cancer is not a life or death matter, the procedure for the dermatologist would naturally be modified as compared with those who treat visceral cancer." Another comment was: "In my specialty as a dermatologist I tell the patient he has cancer after biopsy. I also assure him that cancer of the skin is not so serious as internal cancer because the former can easily be removed and checked for recurrence." Sixty per cent of the psychiatrists favor telling the patient he has cancer. Several of the psychiatrists remarked, however, that they do not see many cancer patients and their answers represent what they think should be done.

TABLE 3.—*Preferences for and Against Telling Patient, by Type of Practice*

	Always Tell or Usually Tell, %	Never Tell or Usually Do Not Tell, %
Dermatology-Syphilology	94	6
Psychiatry-Neurology	60	40
Surgery	41	59
Academy of General Practice	30	70
Nonspecialty group	25	75
Internal Medicine	21	79
Obstetrics-Gynecology	19	81
Radiology	12	88

The figure gives a graphic comparison of the specialty groups, showing the percentage of physicians in each group who tell the patient he has cancer. The specialists on the right hand side of the chart, that is, those who rarely tell the patient, tend to see the patient in the later stages of the disease or are responsible for terminal care. According to our results, the radiologists are the least likely to tell patients they have cancer.

All physicians were asked to list reasons that might cause them to disregard their usual practice of telling or not telling. Most men listed several reasons. The most frequent reason for not telling the patient when the usual practice was to tell was the danger of an unfavorable emotional reaction. The next most frequent reason was a request of the patient's family. When the usual practice was not to tell, the commonest reason for telling the patient was his refusal of necessary treatment. The second was the special need of some patients to plan for the future.

ADDITIONAL COMMENTS OF PHYSICIANS

In addition to answering the specific questions in the questionnaire, many physicians added pertinent comments. Several stated that it was difficult to express their usual practice within the narrow confines of the questionnaire and emphasized the difficulties of answering in generalities. Some stated that the word "cancer" should never be used but that the physician should use such terms as "abnormal tissue growth" or "tumor." In view of the specific information now being given to laymen about cancer, it is possible that such subterfuge may engender in the patient a deep and undermining distrust of his physician. Many specialists stated that they often left the decision in the hands of the referring physician. One of the most frequent comments was that, although the patient himself is not told, a responsible member of the family should always be told.

The opinions expressed in the additional comments closely paralleled the answers to the specific questions of the questionnaire. The majority who made additional comments stated that the patient should not be told. A few of these comments are as follows.

1. It is bad enough to have cancer, and the physician should not rob the patient of what little pleasure may be left in life for him. I can see at no time any reason why the patient should know he has cancer. The dread of the return of the disease, even if the patient is cured, is horrible.

2. I never tell the patient he or she has cancer no matter how strong or stable they are emotionally; very, very few of them are equal to standing the shock of being told the truth. If they don't know definitely—that is, so long as the doctor doesn't tell them the truth—they still have a ray of hope that it might be something else, no matter how much they think they have cancer.

3. During these times I never tell a patient he has cancer. The common people today are educated on cancer and other medical conditions to the extent that cancerophobia, poliophobia, and many other psychological disorders exist in our general population. This is an evil, and this evil is one of the greatest seen in practice today. One of my patients was sent to a hospital where he was told that he had cancer of the tongue. Before I saw him he had had this lesion some time and had worked every day. He was a great baseball fan in apparently good health and doing well. He went by himself happily to the hospital on my advice. When he learned the diagnosis he came home and got in bed. He had to be accompanied to the clinic the few times he attended before his death. He would not eat and lost interest in everything. I feel that his death was precipitated by causes of which cancer played only a part. Some medical education to the general public is in order, but I feel now that the program is going further than it was intended. The programs are defeating the purpose of medical education to the general public. Some of these programs are taking on the effect of demagogy in the interest of the societies which sponsor them rather than to render simple and helpful information which is nonconfusing for the public good.

4. I feel strongly against letting the patient know he has cancer! To all people, intelligent or not, the word cancer means a death sentence, and, even if you meet an occasional patient who insists on knowing the worst and says that it will not affect him one way or another, he will be mentally affected by knowing the worst.

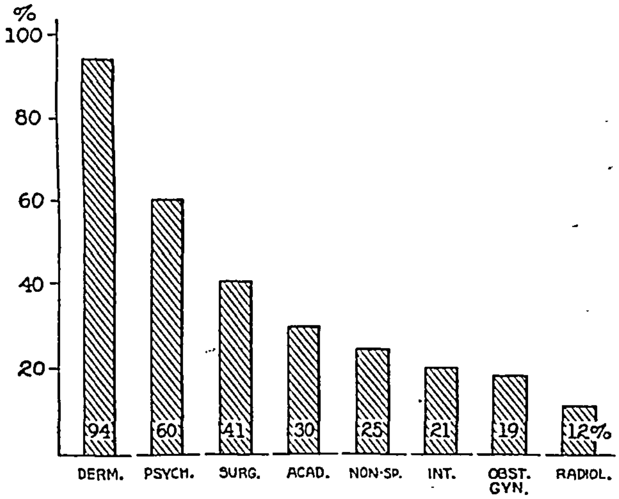
5. The patient should not be told he has cancer. The art of the practice of medicine meets no greater test than the problem under discussion. Some physicians exhibit a sadistic satisfaction in telling the patient bad news. Such doctors, while not able to save life by curing disease, destroy the spirit, which is even a greater failure. The way some physicians handle patients and relatives in the presence of cancer suggests that as doctors they are good blacksmiths.

6. The only justification for telling a patient that he has cancer is the failure of all other persuasion to enlist the full cooperation of the patient as to the indicated therapeutic procedure. This is a rare circumstance.

On the other hand, some physicians strongly urge that the patient should always be told if he has cancer. These comments were much less frequent than those expressing the opposite point of view. Some of these statements follow.

1. The time has arrived when it is impossible to fool intelligent people. The public is getting so well informed that the patient knows from the treatment advised and used that they are being treated for cancer.

2. I always tell the patient he has cancer. In forty years I have had only two instances where the full truth was not well received. You can create distrust in the profession or bitter loss of faith in the family if deception is practiced by anyone. All patients can bravely face even death if they know the truth and trust the honesty of the one they have selected to aid. They condemn their physician or even their close family if they discover they have been deceived and will not even trust a favorable prognosis should such be possible. To deceive a patient or even evade a real fact of certain death, is to torture the intelligence of those who will know, even if it be at the very last, that they could trust no one.



Percentage of members of specialty groups who tend to tell patients they have cancer.

3. The patient needs a deep confidence in the physician. This is obvious. It is less obvious but equally important that the physician have a deep respect of the patient. Sharing with the patient the fact that he has cancer, a malignant condition, can and should be evidence that the doctor has this respect and confidence in the patient's capacity to know and live with the truth. Failure to do this means the doctor does not have this feeling, and needs to shield himself. The doctor-patient relationship can be strengthened when there is mutual sharing and knowing together a painful truth. Otherwise a painful barrier can be built up.

4. It has been my experience that patients who have a curable cancer accept the truth very well. In view of the fact that a close and long follow-up is so essential, I find that these patients are extremely cooperative. To insist that patients return at regular intervals when they are ignorant of the true diagnosis, is only to arouse suspicion plus psycho-emotional maladjustment.

COMMENT

This study shows that most Philadelphia physicians do not tell patients they have cancer. We did not try to determine whether a trend toward telling was discernible in the practice of the profession. One might anticipate a trend toward telling as a result of the education of the layman about cancer. On examination of the additional comments to the questionnaire there is no definite indication that such a trend is occurring.

It is interesting that over 90% of the dermatologists usually tell patients they have cancer. Almost certainly they tell because they consider skin cancer a relatively benign disease. The fact that physicians treating visceral cancer usually do not tell may indicate that these physicians consider visceral cancer a lethal disease, despite the great amount of writing to the effect that visceral cancer is curable when it is treated early. It might be inferred, therefore, that if the cure rates for cancer improve significantly, many physicians will swing over to an affirmative view.

The study shows that a great deal more needs to be done in determining the mental and emotional reactions of cancer patients and how these reactions should be handled by the physician. Renneker and Cutler [2] in a recent study stated that all of a group of 50 patients with cancer of the breast actually knew they had cancer even if not told by their physicians. These patients were relieved when they had someone who would talk to them about cancer. On the other hand, in our study three instances of suicide were reported to have been the direct result of patients being told they had cancer. (Two instances were reported by one physician, and one instance was reported by another.)

We do not propose to give an answer to this perplexing problem. Our own opinion, after several years of study concluding with this investigation, might be best summed up in the words of one of the internists who commented on the questionnaire as follows: "Most patients and almost all people who have discussed this problem with me have expressed a hope that they would be told the truth. Most families of patients, on the other hand, have actually asked that the patient not be told. In theory I believe that we should tell all patients except when there are definite reasons for not doing so. I think that those reasons need clarification. I do not know which patients I might make feel worse by telling, and, therefore, I do not know with confidence which patients to tell."

SUMMARY AND CONCLUSIONS

A sample of 444 physicians in Philadelphia County were questioned concerning what they told patients with cancer. The response from the questionnaire was excellent and indicated a keen interest in the problem. Eighty-nine per cent of the physicians who were questioned responded, and 82% gave answers complete enough to tabulate. Seventy per cent of the physicians either never tell a patient he has cancer or usually do not tell; 30% either always tell or usually tell.

When the replies are analyzed according to specialties, the most striking variation concerns the dermatologists. Ninety-four per cent of the dermatologists either always or usually tell the patient he has cancer, and only 6% never or usually do not tell. This difference between the policy of dermatologists and the other groups can be explained by the fact that dermatologists treat types of cancer that have a more favorable prognosis than cancer treated by other physicians. This point of view is supported by comments added to the questionnaire by several dermatologists. In view of the striking contrast between the dermatologists and the other groups, it seems reasonable to believe that the physicians treating visceral cancer do not tell patients they have cancer because they consider the prognosis unfavorable. The question of the curability of cancer was not considered specifically in the questionnaire, and the above conclusion is based on our interpretation of the data.

Studies are needed to determine which patients with cancer might benefit by being told they have cancer and which might not. In view of the tremendous amount of information about cancer given to laymen, it seems that the medical profession will be forced to study this problem extensively.

Cancer Mortality Trends.—In the past two decades the trend of mortality from the malignant neoplasms (cancers and allied conditions, such as leukemia) has been characterized by rather marked sex differences. The recorded rate from this cause of death has been decreasing among women and increasing among man. . . . Among white females . . . the death rate from malignant neoplasms dropped 12% between 1940-1942 and 1950-1952. . . . In contrast, the mortality among insured white males showed an increase of about 5%. . . . As a result of these divergent trends, the death rate for males is now 28% above that for females, whereas 10 years earlier it was only 8% higher; 20 years ago the male rate was actually the lower of the two by 3%. Virtually every age group among white women has shared in the long-term decline in the death rate from malignant growths. In the past decade alone the reduction was as much as 21% at ages 35-44 and was nearly as large at 25-34 years; even at ages 65-74, where the improvement was smallest, it amounted to 9%. Not only is the cancer death toll among women decreasing, but the rate of decline has accelerated. There can be little doubt that real progress is being made in the control of cancer among white women. Quite different, however, is the record for white men. Their death rates from malignancy are higher now than two decades ago at every age group. As a consequence, in the age range 25-54, where the female death rates from malignant neoplasms are higher than those for males, the sex difference has greatly diminished in the past 20 years; at ages 55-74, where the rates for males are the higher, the difference has widened considerably. At ages under 25 the general trend of cancer mortality has been upward in both sexes, primarily because of the increase in the recorded death rate from leukemia. . . . In part, the rise in the recorded death rate from malignant neoplasms among males reflects simply the more frequent detection of the disease, as a result of improved methods of diagnosis and an increasing number of autopsies. Inasmuch as a higher proportion of inaccessible cancers occurs in males than females, undetected cancers in the past were more common among males, and such deaths were ascribed to some other cause. Conversely, the improvement in diagnosis has brought to light more cases among males than females. Respiratory cancer is a conspicuous example of the influence of these factors.—Sex Differences in Cancer Mortality Trends, *Statistical Bulletin,* Metropolitan Life Insurance Company, July, 1953.

RESULTS OF SURGICAL TREATMENT OF BREAST CANCER AT JOHNS HOPKINS HOSPITAL, 1935-1940

Edward F. Lewison, M.D., Frances H. Trimble, M.D.
and
Paul C. Griffith, M.D., Baltimore

Through the years the concept of radical breast surgery was held by many men, yet it remained for William Stewart Halsted to develop the modern and complete operation for breast cancer. Such celebrated surgeons as Le Dran and Petit of France, Volkmann, Billroth, and Heidenhain in Germany, Moore, Lister, and Banks in England, and S. W. Gross and Willy Meyer in the United States were among the leaders of their period, but precedence for radical mastectomy has been uniformly bestowed on Halsted.

In the Johns Hopkins Hospital reports for 1890 and 1891 within the text of an article on wound healing Halsted[1] first published a summary of 13 cases of breast cancer treated by his initial technique of radical surgery. "About eight years ago (1882) I began not only to typically clean out the axilla in all cases of cancer of the breast but also to excise in almost every case the pectoralis major muscle, or at least a generous piece of it, and to give the tumor on all sides an exceedingly wide berth." All tissues were to be removed in one piece—dissection in continuity. Later Willy Meyer (1894)[2] advocated the routine removal of the pectoralis minor muscle, an amendment acknowledged by Halsted and readily accepted in his subsequent surgical technique.

In the ensuing years many skillful surgeons have contributed modifications to the basic principles of this classic operation. Today radical mastectomy remains the operation of choice in most cases of cancer of the breast. Yet there has recently arisen among competent observers a difference of opinion as to the effectiveness of radical mastectomy in the treatment of cancer of the breast. Contributing to this present state of doubt and dilemma are many conflicting voices of preeminence.

Haagensen and Stout (1943)[3] have clearly shown that certain cases of advanced breast cancer must be regarded as "categorically inoperable." Pack (1951)[4] and his courageous colleagues call for total mastectomy for cancer of only one breast—prophylactic bilateral mastectomy. McWhirter (1949),[5] a resolute radiotherapist to the Royal Infirmary of Edinburgh, believes that more lives can be saved in unselected cases by simple mastectomy combined with superior x-ray therapy. Gordon-Taylor (1948),[6] Wangensteen (1950),[7] and Urban (1952)[8] fearlessly explore the mediastinum and neck in an extensive thoracocervical dissection known as the superradical mastectomy. This heroic surgery is the contemporary consummation of somatic reduction and must await the test of time for its ultimate assessment. The leading exponents of ultraradical surgery are seeking "second look" operations, whereas Park and Lees (1951)[9] have recently intimated that it is extremely doubtful if the survival rate is influenced by treatment at all. In commenting on our inability to control breast cancer mortality, McKinnon (1951)[10] claims that "the failure of early treatment to reduce mortality shows that spread of remote metastases occurs before interference is possible." Perhaps a survey of the operative treatment of breast cancer at a large teaching hospital that has been closely linked by history and tradition with the development of radical mastectomy might be helpful in placing this perplexing problem in the proper perspective.

MATERIAL AND METHODS

The study consisted of a long-term follow-up survey of all patients with primary breast cancer who received surgical treatment at the Johns Hopkins Hospital during the period 1935 to 1940 inclusive. In this survey a total of 255 female inpatients, both private and ward, Negro and white, entered the hospital with a clinical diagnosis of breast cancer. Two hundred and twenty of these patients subsequently underwent operation; 14 were treated by simple mastectomy, 204 by radical mastectomy, and 2 by local excision (one patient having pulmonary metastases and the other refusing further treatment).

The remaining 35 patients were treated by radiotherapy alone, were considered to have lesions hopelessly advanced and beyond treatment, were discharged without treatment, or refused treatment. No further follow-up of these patients was undertaken. An indeterminate number of outpatients with primary, recurrent, or metastatic breast cancer were seen in the large and active outpatient department of the Johns Hopkins Hospital, but there were no statistics available for this group of unrecorded patients. Male patients and patients with malignant lesions of the breast other than primary breast cancer were excluded from this study.

From the Breast Clinic, Division of the Tumor Clinic, Department of Surgery and the Department of Pathology, Johns Hopkins Hospital and University.

This clinical investigation was supported in part by research grants from the S. Kann Sons Foundation, the Alexander and Selma H. Hecht Foundation, and the Marcelle Fleischmann Foundation (through the Maryland Division of the American Cancer Society).

The obvious difficulty of tracing patients who had been operated upon some years previously was, of course, inevitable but not insurmountable. By perseverance and pursuit a successful follow-up was obtained in 208 patients, or 94.5% of the present series. All patients lost to follow-up or those dying of intercurrent disease were considered to be dead of cancer for purposes of this computation.

Because of realization of the great variability in the natural history of breast cancer, with its unpredictable tendency to remain quiescent for long periods of time or to metastasize early, the criteria of operability at this hospital have usually been flexible but lenient and tempered by individual judgment. The rigid but valuable standards of operability published at a later date by Haagensen and Stout (1943) [3] were not strictly adhered to during the period of this survey.

The diagnosis was verified by pathological examination in every patient. One of us (P. C. G.) has recently reviewed the histological material from the 64 cases of breast cancer in which the patients were known to have survived 10 years or longer to correlate, if possible, histological structure with clinical course.

TABLE 1.—*Five-Year End-Results of Surgical Treatment for Breast Cancer, 1935-1940*

Type of Treatment	Stage of Disease	No. of Patients	Living and Well No.	Living and Well %	Living with Recurrence No.	Living with Recurrence %	Total Survivors No.	Total Survivors %
Radical mastectomy	Breast alone	78	44	56.4	6	7.7	50	64.1
	Breast and axilla	126	35	27.7	5	4.0	40	31.7
	Total	204	79	38.7	11	5.4	90	44.1
Simple mastectomy	Breast alone	5	2	40.0	..	...	2	40.0
	Breast and axilla	9	2	22.2	..	...	2	22.2
	Total	14	4	28.6	..	...	4	28.6
Local excision	Breast alone	1	1	100.0	..	...	1	100.0
	Breast and axilla	1	..	....	..	...	0	0.0
	Total	2	1	50.0	..	...	1	50.0
	Total	220	84	38.2	11	5.0	95	43.2

Comparison of treatment and survival rates is usually based on the clinical staging of the disease. However, this code of classification by clinical stages in cancer of the breast is difficult, depends upon individual judgment, and varies considerably in accuracy from patient to patient and from site to site within the breast. Despite the desire for uniformity in classifying clinical stages, the present series was divided arbitrarily into only two groups, namely, (1) those patients without axillary metastases by microscopic examination and (2) those patients with axillary metastases by microscopic examination. In the few cases in which the axillary contents were not available for pathological examination, it was necessary to resort to classification by clinical stages alone.

RESULTS

Clinical Study.—In discussing the results of radical mastectomy, Halsted (1907) [11] stated that in the ultimate survival of the patient "the variety of the cancer, the time elapsed since its appearance, the degree of outlying involvement, the activity of the gland (lactation, age of patient), the thoroughness of the operation, are important factors." Of these variable factors of importance, the presence or absence of axillary involvement appears to be of paramount and decisive influence in determining the prognosis of patients with breast cancer. Table 1 records the five-year survival rate at this hospital for all patients with breast cancer operated upon from 1935 to 1940 inclusive.

The total five-year survival rate for all patients regardless of the type of surgical treatment or the stage of disease was 43.2%. The so-called clinical "cure" rate—patients living and well without discernible evidence of recurrence or metastases at the end of five years—was 38.2%. Axillary metastases were noted in 62% of patients who were subjected to radical mastectomy. When surgical treatment consisted of radical mastectomy, almost two-thirds of the patients without axillary metastases were still alive five years after operation, whereas only one-third of the patients with axillary metastases were alive at the end of this period.

Using a more ambitious yardstick the 10-year end-results of surgical treatment are indicated in table 2. The over-all 10-year survival rate was 29.1%. If cancer remained confined to the breast alone, however, the 10-year survival rate was 47.6%. On the other hand, if breast cancer had already spread to the adjacent axilla, the 10-year survival rate then fell to 17.6%.

The average age at operation of all patients with breast cancer in this series was 51.9 years. The average age of patients having breast cancer without axillary metastases was 53.7 years, whereas the average age of patients having breast cancer with axillary metastases was 50.9 years. The youngest patient in this series was 27 years old and the oldest was 90 years old. Of the several cardinal factors that could conceivably modify the five-year survival rate, age appeared to be of some tangible prognostic significance. The over-all five-year survival rate for patients in the present series was 43.2%, whereas the five-year survival rate computed for patients under the age of 40 was only 29.6% (table 3). Thus, a comparatively poor prognosis for young women was demonstrated in this small series, both when axillary metastases were present and when they were not. It should be carefully noted, however, that the breast and axilla were involved in 136 patients, or 61.8% of the entire series. In the limited group of women under the age of 40 the breast and axilla were involved oftener, in 70.4% of the patients, thus indicating a more advanced disease at the time of operation.

During the period of this study (1935 to 1940) radiotherapy was still a relatively new departure, and in the light of today's technique this early therapy may be considered inadequate and unsatisfactory. Although steady progress took place during the 1930's, the most marked advances have occurred only in the past decade.

TABLE 2.—*Ten-Year End-Results of Surgical Treatment for Breast Cancer, 1935-1940*

Stage of Disease	No. of Patients	Living and Well		Living with Recurrence		Total Survivors	
		No.	%	No.	%	No.	%
Breast alone........	84	34	40.5	6	7.1	40	47.6
Breast and axilla...	136	23	16.9	1	0.7	24	17.6
Total.............	220	57	25.9	7	3.2	64	29.1

TABLE 3.—*Five-Year End-Results of Surgical Treatment for Breast Cancer in Women Under Forty*

Stage of Disease	No. of Patients	Living and Well		Living with Recurrence		Total Survivors	
		No.	%	No.	%	No.	%
Breast alone.....	8	4	50.0	..	....	4	50.0
Breast and axilla	19	2	10.5	2	10.5	4	21.0
Total..........	27	6	22.2	2	7.4	8	29.6

The criteria for radiotherapy in breast cancer—then and now—reveals a disconcerting lack of uniformity. The decision to use radiotherapy as an adjunct to surgery either preoperatively or postoperatively appears to have been made independently according to the custom of each individual surgeon. Thus, treatment given at random and based on ill-defined and intangible clinical judgment results in uncritical conclusions that are difficult to assess.

Preoperative radiotherapy alone was given to 40 patients, 77.5% (31 patients) of whom were found to have axillary metastases at the time of operation. The five-year survival rate for these patients receiving preoperative radiation was 25% (10 patients). Postoperative radiotherapy alone was given to 60 patients, 34 (56.6%) of whom were found to have axillary metastases at the time of operation. The five-year survival rate for these patients receiving postoperative radiation was 30% (18 patients). Thus, it would appear from these survival rates that neither preoperative nor postoperative radiotherapy was of benefit in increasing survival in this small series.

It is well, however, to suggest that patients who seemed to have had the most advanced disease or those who were considered by the operating surgeon as having the poorest prognosis were usually the most likely prospects for added radiotherapy. There is sound reason to believe that, if strict criteria of operability are observed, radiotherapy as an adjunct to surgery may actually be unnecessary. Also, if radical mastectomy failed to remove cancer in toto, then the amount of postoperative radiotherapy that could be safely administered to a thin veil of skin overlying a denuded chest wall may be entirely inadequate for sterilizing the field or stimulating the host reaction to prevent the appearance of skin recurrences. Nevertheless, current practice at this hospital favors the use of postoperative radiotherapy in all patients with axillary metastases.

HISTOLOGICAL STUDY

To determine if there might be any notable histological characteristics of the breast carcinomas that were removed from the 64 patients who had undergone surgery and had survived 10 years or more, the histological sections from these cases were reviewed. This differs from the usual procedure followed in histological evaluation of prognosis of breast carcinoma where microscopic sections are reviewed without knowledge of the clinical course. No attempt was made to compare histologically this apparently long-survival series with a comparable short-survival series, although this would be of considerable interest.

The number of microscopic sections available for study from each of the 64 cases ranged from 2 to 18, with a median number of five sections. From one to 11 lymph node sections with a median of three sections were available for examination. In examination of the sections the following factors were noted: lymph node involvement, vessel invasion, pattern, tubule formation, cellular and nuclear morphology, hyperchromatism, mitoses, necrosis, and desmoplasia. For the most part Stewart's (1950)[12] histological classification of breast cancer was used. Table 4 shows the variety of histological types, tubule formation, and lymph node metastases found in this series of 10-year survivals.

TABLE 4.—*Histological Classification of Breast Carcinoma in Sixty-Four Patients Known to Have Survived Ten Years or Longer*

Type	No.	%	Tubules Present	Nodes Involved
Duct Carcinoma				
Infiltrating with fibrosis (scirrhous)	26	40.6	12	10
Papillary with infiltration.........	2	3.1	2	1
Medullary carcinoma with lymphoid infiltration	5	7.9	1	3
Mucoid carcinoma..................	2	3.1	2	1
Infiltrating "comedo" type........	8	12.5	1	2
Infiltrating carcinoma (mixed or unclassified *)	15	23.0	8	5
In situ duct carcinoma............	1	1.5	..	..
Anaplastic carcinoma................	2	3.1	..	..
Well-differentiated adenocarcinoma.	1	1.5	1	1
Lobular carcinoma...................	1	1.5	..	1
Equivocal carcinoma †..............	1	1.5	..	..

* It was not well demonstrated in the sections available that all these arose from ducts, but their general pattern was strongly suggestive.

† A positive tissue diagnosis of breast carcinoma had previously been made from other sections of the operative specimen than those available at this time.

In general it may be stated that no histological characteristics that could be correlated with the prolonged clinical course were found in a review of these 64 carcinomas of the breast from women known to have survived 10 years. There were, however, several results of the study that warrant mention. It was notable that in only one case was the diagnosis of in situ carcinoma made, the other 63 cases showing definite stromal infiltration. In 24 cases (37.5%) metastases were revealed in one or more lymph nodes. Not infrequently other findings also generally regarded as purporting a poor prognosis were noted, such as skin invasion and metastases to muscle. Tubule formation indicating a favorable prognosis was absent in 41 (64%) cases, as noted in table 4. It is interesting that adenocarcinoma, "comedo" carcinoma, and medullary carcinoma with lymphocytic infiltration, the histological types of duct carcinoma usually associated with a better prognosis, were not especially conspicuous in this series. It is remarkable that the proportion of the histological types of breast carcinoma noted in this long survival series is about the same as the proportion seen for all cases of breast carcinoma. These observations demonstrate that, at least in this series, the histological appearances alone would not have allowed one to prognosticate the 10-year survival that ensued.

COMMENT

There are few fields in surgery with more pitfalls for the statistically unwary than the appraisal of end results in the treatment of breast cancer. Almost 50 years ago Halsted (1907)[11] commented that "It is especially true of mammary cancer that the surgeon interested in furnishing the best statistics may in perfectly honorable ways provide them. The most conscientious man may refuse to operate upon any but favorable cases. . . ."

Real benefit, however, can be derived from a review of the end results of treatment if a great deal of scrupulous care and strict uniformity is observed in recording and reporting clinical studies. In this effort to eliminate the personal "built-in bias," all results should be accurate and intelligible, comparable with similar studies the world over, and indicative of genuine improvement (if such be the case) over alternative methods of treatment or even over the natural life history of the disease itself if no treatment was given at all. The validity of comparative results must be based upon a common language applicable to a specific type of cancer, operative or radiotherapeutic procedure, selection of cases and uniformity of reported end-results. Decisive factors other than treatment do, of course, influence survival and prognosis in cases of breast cancer. Such important antecedent factors as those indicated by Lewison and Allen (1953)[13] (heredity, fertility, age, marital status, pregnancy, and lactation), as well as, grading of malignancy, tumor size, position and rate of growth, stage of disease, host resistance, duration of disease, selection of patients, and criteria of operability present many problems that must be successfully solved before one can precisely determine the best treatment plan for each patient. As noted by Smithers and his colleagues, (1952)[14] "Comparisons of overall results obtained in the best treatment centres which do provide the basic data on which absolute survival rates can be calculated show that a steady improvement has occurred over the years but do not yet provide conclusive evidence that the slight differences observed in groups treated at about the same time are due to the treatment methods advocated and not to variations in the material treated."

The results of radical mastectomy in the treatment of cancer of the breast at the Johns Hopkins Hospital were first reported by Halsted in 1907. Excluding 65 patients in whom simple surgery was found more suitable, there remained 232 patients treated by radical surgery. In about 50% of these patients, supraclavicular neck dissection was combined with radical mastectomy. Although the end-results in 18 patients were unknown, these untraced patients were considered to be dead of the disease. The three-year survival rate for this early period was 38.3%, with a relative "cure" rate of 32.3%. The five-year survival rate (revised) was 28.9%, with a relative "cure" rate of 24%. It is of interest to note that the statistics of the present series represent an improvement in end-results, which are almost 15% better than the earliest Halstedian era.

Lewis and Rienhoff (1932),[15] in a most exhaustive study, reviewed a series of 950 consecutive breast cancer cases observed at the Johns Hopkins Hospital during the 42 year period 1889 to 1931. During this long timelag in follow-up, it is indeed unfortunate but readily understandable that 22% of the patients were completely untraced. Considering only 420 patients in whom accurate survival information was available, the five-year survival rate following radical mastectomy was computed to be 18.1%.

A survey of the results of ward patient treatment at the Johns Hopkins Hospital for the 11 year period 1932 to 1942 was carefully reviewed and reported by Jones (1949).[16] Of 304 ward patients with breast cancer, 52 (17%) were considered unsuitable for radical mastectomy and 31 (10%) were lost to follow-up. The five-year survival rate (excluding those patients lost to follow-up) was 34%. However, considering all patients (those lost to follow-up being computed as having died of cancer), the five-year survival rate would then be revised to 29.3%—a result almost identical with the initial results of Halsted.

A unique and particularly interesting study of 298 consecutive cases of breast cancer treated by radical mastectomy was reported by Finney, Merkel, and Miller (1947).[17] All patients were the private patients of four distinguished surgeons who received their training either directly or indirectly as disciples of Dr. Halsted. Their five-year survival rate (computed exclusive of those patients lost to follow-up and postoperative deaths) was 49%. Revising this over-all survival to include total patients, the five-year survival rate was then 45.3% whereas the 10-year survival rate was only 17.4%.

These statistics are indeed provocative but provide no ready answer to the unpredictable behavior of breast cancer. Why this similar group of patients, Baltimore's beau monde—operated upon by a quartet of Halsted's most skillful students—should have a five-year survival rate almost identical with the present Johns Hopkins series yet have a 10-year survival rate that is scarcely comparable remains a caprice of biostatistics. As suggested by Lees and Lees,[18] data presented in a purely statistical fashion should not give the misleading impression of rigid mathematical certainty. "They should simply define with accuracy and with known uncertainty what would otherwise have been more or less inaccurate impressions."

Today national and international cancer societies are imploring greater standardization in reporting cancer statistics. It is, of course, most desirable that criteria for determining the clinical stages of breast cancer should be based upon a careful physical examination supplemented by simple instrumentation which is available to all physicians. While urging the doctrine of uniformity, this report in itself is an exception. The accuracy of hospital histories being notoriously variable, the inconsistency that so often besets us is well illustrated by the present series. Despite our best intentions of coding breast cancer by stages as recommended by the American Cancer Society and the International Union Against Cancer, we found the hospital case records generally inadequate for this purpose. However, we hope that future surveys from this hospital will report the clinical stages in accord with the following code:

Primary Site:

0	No tumor
1	Tumor infiltrating the primary organ site
2	Tumor of relatively larger size, infiltrating the primary organ site and not extending beyond the adjacent soft tissues
3	Tumor widely infiltrating the primary organ site and extending to neighboring organs
4	Tumor extensively involving adjacent soft tissues or organs

Metastases:

0	None
1	Regional lymph nodes slightly enlarged, discrete and movable
2	Regional lymph nodes considerably enlarged, and fixed either to one another or to adjacent structures
A	Clinical stages confirmed microscopically

A joint committee on reporting cancer end-results has recently recommended "Rules For Reporting Five-Year End Results of Persons with Malignant Neoplastic Diseases." This committee was composed of representatives of the American College of Surgeons, the College of American Pathologists, the American College of Radiology, the American Cancer Society, and the National Cancer Institute.

SUMMARY AND CONCLUSIONS

A long-term follow-up survey of 220 patients with primary breast cancer who were operated upon at the Johns Hopkins Hospital during the period 1935 to 1940 inclusive is reported. A successful follow-up was obtained in 208 patients, or 94.5% of the entire series. All diagnoses were carefully reviewed and verified by histological examination. A special histological study of the surgical specimens from 64 patients known to have survived 10 years or longer was undertaken.

Two hundred and four patients (93%) were treated by means of radical mastectomy, 14 patients (6%) were treated by means of simple mastectomy, and 2 patients (1%) received only local excision. The total five-year survival rate for all patients regardless of the type of surgical treatment or the stage of disease was 43.2%. The five-year clinical "cure" rate—patients living and well without discernible evidence of recurrence or metastases—was 38.2%. The five-year survival rate computed for patients under the age of 40 was only 29.6%, thus indicating a comparatively poorer prognosis for younger women. The five-year survival rate for patients without axillary metastases by microscopic examination in the nodes examined, was 64%; whereas the five-year survival rate for patients with detected axillary metastases was only 31%. The total 10-year survival rate was 29.1%.

The problem of preoperative and postoperative radiotherapy is discussed. A review of the cases of 64 patients with breast cancer who survived 10 years or more failed to reveal any histological characteristics that could be correlated with a favorable prognosis or long-time survival. Despite current clinical experiments with both more conservative and more radical surgical procedures, the classical Halsted radical mastectomy sets a high standard of surgical treatment and remains the operation of choice in most cases of breast cancer.

Mercury Poisoning.—In industry, mercurial poisoning gives rise to symptoms slowly and insidiously: acute poisoning does not occur. The early symptoms include a metallic taste, salivation and tenderness of the gums. The gums are swollen and bleed easily, and the teeth may fall out: it is not easy to distinguish an early mercurial gingivitis from the pyorrhoea of a neglected mouth. Rarely, a blue mercurial line is seen on the gums, less conspicuous than the line in lead poisoning. The most characteristic symptom is mercurial tremor, one of the oldest known involuntary movements in the history of medicine. It is moderately fine and may be interrupted every few minutes by coarse shaking movements. It usually begins in the fingers, but the eyelids, lips and tongue are affected early. As it progresses, the arms and later the legs are affected so that it becomes very difficult for a man to walk about the workshop and often he has to be guided to his bench. At this state the tremor is so obvious that it is known to the layman as the hatters' shakes. The tremor often passes away if the patient is removed from his work before it has become serious. . . .

In the manufacture of clinical thermometers and in laboratories where mercury is handled extensively, benches should be covered with a smooth impervious surface sloping so as to drain the mercury into a suitable receptacle at the lowest point. The walls and floors should be of impervious material and the floor should be cleansed at the end of each day's work. Thermometers should not be filled without suitable exhaust-ventilation for the removal of mercury vapor. Overalls, mess-rooms and washing facilities should be provided. The mouth and pharynx should be frequently rinsed with a mouth-wash, and the teeth cleaned with a soft tooth-brush and a dentifrice. Periodical medical and dental examination can achieve a great deal, especially by emphasis on the proper hygiene of the mouth. Cavities in carious teeth should be filled, sharp angles smoothed, and stumps and teeth irremediably decayed extracted.—D. Hunter, M.D., Occupational Diseases with Neurological Symptoms and Signs, *The Practitioner*, July, 1953.

THE FAMILY PHYSICIAN AND HEART DISEASE

INFLUENCE OF CLIMATE AND IATROGENIC ASPECTS

CHAIRMAN'S ADDRESS

Richard A. Mills, M.D., Ft. Lauderdale, Fla.

A prominent cardiologist in the South asked a group that included several family physicians, "Would you want a general practitioner to attend your grandmother if she had a heart attack?" His answer was no. My answer is yes. In fact, the family physicians of this nation are doing most of the work of caring for grandmother, not only for heart disease but also for the many other diseases that may occur in her age group. He is most valuable in helping her with her anxieties, frustrations, and worries. He is too often the only physician who will answer a call in the middle of the night to see grandmother or any other member of the family.

If the patient is critically ill, the general practitioner must be sure to call a consultant. He must be very sure, however, that he only consults. The family physician must remain in charge as the attending physician and, if the patient is not doing well, ask the consultant to see the patient again, or, if he is unsatisfactory, call in another consultant. It is extremely important that the modern family physician be well versed in the care of cardiac emergencies, since his snap decision concerning diagnosis and treatment may determine whether or not the patient lives or dies. If the patient survives and is hospitalized, I sincerely hope that the family doctor is not practicing in one of those areas in which he will have to turn the patient over to another physician at the hospital.

CLIMATE AND HEART DISEASE

With the recent increase in life span and the almost complete elimination in this country of all major causes of death except vascular disease, cancer, and accident, an increasingly familiar aspect of the American scene has been the annual pilgrimage of cardiac patients to Florida. In view of the usual benefit derived from this pilgrimage, it must be concluded that, in one sense at least, these patients have found that fabulous fountain of youth whose absence so disappointed Ponce De Leon. Although the majority of persons who seek health in our temperate climates have arteriosclerotic and hypertensive heart disease, those with rheumatic and congenital heart disease have come to Florida seeking health in the more kindly climate.

The patient with rheumatic heart disease who comes to southern Florida comes either to alleviate the distress of his advanced vascular damage or to live in a place where the danger of a potentially damaging flare-up of the active rheumatic state would be minimized. He has ample basis in clinical and experimental observation for his confidence in the ability of the Florida climate to help. White states that "Climate appears to be an important factor in the incidence both of rheumatic infection and the rheumatic type of heart disease. In the northern part of the United States the rheumatic infection and its permanent involvement of the heart are five times more frequent than in the southernmost part of the country." Various comparative surveys have shown that the incidence of rheumatic heart disease in Southern California and Arizona is much lower than in colder areas such as Connecticut and Wyoming.

Careful studies by Saslaw on the incidence of rheumatic fever in native school children in Dade County, Florida, have shown that the incidence in this group is much lower than in the rest of the country except in southern Arizona and Redlands, Calif. Further studies by this group have shown that the incidence of rheumatic heart disease in out-of-state school children in Dade County is much greater than in the native children. This is undoubtedly due to the migration of children with rheumatic disease to this area. The low incidence of rheumatic fever and rheumatic heart disease in the native children in Dade County, Florida, and I am sure that this is also true in the remainder of south Florida, is undoubtedly due to the comparatively low incidence of upper respiratory infections, especially those associated with streptococci. The mildness of the climate allows much more time to be spent out-of-doors than in the northern climate. This distinction is especially true in the winter months. This leads to less crowding indoors and less spread of those upper respiratory infections that do exist. It is well known that crowding increases the incidence of rheumatic fever, and that, too often, it occurs in too many members of the same family.

Although the studies mentioned have shown that fewer persons with congenital heart disease move to warmer climates than persons with rheumatic heart disease, there is no doubt that the relative mildness of the climate and the lower incidence of upper respiratory infections makes the lot of the patient with congenital heart disease in southern Florida a less onerous one. There is less possibility of bacterial endocarditis affecting a congenitally malformed valve in the mild climate. The lessened metabolic requirements in the warmer climate undoubtedly diminish the burden for the congenitally inadequate heart that has difficulty maintaining its compensation. Although the persons with rheumatic and congenital heart disease benefit greatly from the mild climate of southern Florida, most of the patients with heart disease who seek help there have hypertensive and arteriosclerotic disease. This sufferer benefits from the climate in many ways. For one thing, he is less susceptible to upper respiratory and pulmonary infections. These infections, in a more unfavorable environment, too often are the precipitating cause of cardiac failure in a person who has been just getting by.

Read before the Section on General Practice at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

In colder environments, there is a constant stimulation to the thermal regulatory centers, with consequent metabolic stimulation. Along with this stimulation, there is vascular constriction and increased production of the adrenal steroids with their known deleterious effect on the vascular system. The angiospasm resulting from cold is, of course, a well-known phenomenon. Its effect on the patient with angina is too often to increase markedly the incidence of his anginal episodes to the extent that many such sufferers are forced to spend all of their winters indoors. Such persons always benefit greatly from the milder winter climates in south Florida.

The patient with peripheral vascular disease also benefits a great deal from the milder climate. It has been strikingly evident to me that, although many of my patients have moderately severe to severe impairment of their peripheral circulation, their complaints are surprisingly few. Many of these persons suffered considerably because of the impairment of their peripheral circulation before they came to Florida, and there is no doubt that the lack of stimuli to angiospasm with its accompanying disability is due to the milder weather.

Despite the undoubted benefit derived by the person with arteriosclerotic and hypertensive heart disease who flees from the colder northern weather to the more moderate climate, no studies have been made that are comparable to the one made in rheumatic fever. Surprisingly enough, the study that demonstrates best the effectiveness of warm weather in reducing mortality in heart disease is the work done by Brown and Pearson. They analyzed the relationship between mortality due to heart disease and the mean temperatures at various times of the year in New York City. They used mortality statistics for all types of heart disease for the 10 years from 1934 to 1944 and the mortality due to coronary artery disease for the 5 years from 1940 to 1944. These investigators found that there was an 18.8% increase in the deaths due to heart disease in the colder months. They were able to show that the deviation of the average temperature from the yearly average in a month varied inversely with the number of deaths due to all forms of heart disease and also to coronary artery disease. Although the complaint is often made that discomfort in hot weather is due to humidity rather than heat, similar studies showed no direct relationship between the rate of deaths due to heart disease and the humidity, and this was specifically true of deaths due to coronary artery disease. Even though similar studies are not available for southern Florida, comparison of the temperatures at West Palm Beach weather station with those in New York show that the daily maximal, minimal, and mean temperatures in New York City during the months of June, July, August, and September, were of the same order of magnitude as those reported by the West Palm Beach weather station during the months of November, December, January, February, March, and April. May and October, although somewhat warmer, are not appreciably so, since the averages are only 3 to 4 degrees higher in those months than at the peak of the New York summer, July, when according to the mortality statistics the deaths due to heart disease are minimal. Studies in southern Florida similar to those made in New York are not practical for several obvious reasons. The population varies a great deal between summer and winter, and mortality statistics using the so-called fixed population as a basis would be inaccurate. In addition, the many persons with known heart disease who come to this area because of the mild winters, and who die here despite the climate, would also render the results unreliable. In comparison of cardiovascular death rates in states with more stable populations, it is found that the rate in New Hampshire is 644.7 per 100,000, but 231.3 per 100,000 in New Mexico.

A discussion such as this would be incomplete without mention of the work done by Dr. George Burch on the effect of subtropical climate on congestive heart failure. His studies were made under conditions of controlled temperature and humidity. He found his cardiac patients were very comfortable and did best at temperatures from 68 F to 72 F, averaging 70.3, with humidity ranging from 48 to 72%, averaging 60.2%. When he subjected these patients to temperatures ranging from 99.0 F to 108.3 F, with an average of 104.3, they were extremely uncomfortable and at times acute congestive failure was induced. When the temperature ranges in his experiments are compared with those reported from the West Palm Beach weather station, the temperatures he reported as optimal for comfort, namely, from 68 F to 72 F, are found to be of the same order of magnitude as the mean temperatures for the months of November through April, since these were 68 F to 74.1 F. The relative humidities reported during these months, taken at 1:30 p. m., are close to those reported by Burch as being most comfortable. The temperatures found to be so deleterious, that is, temperatures ranging from 99 F to 106 F with a mean of 104.3 F, are considerably higher than those experienced in Florida and the Caribbean area, since the average maximal temperatures in the hottest months, July and August, never go above 92 F and the means never above 83 F. In his study Burch must have used the temperatures of his home city of New Orleans when he cited temperatures between 99 F and 108 F.

IATROGENIC HEART DISEASE

Another type of heart disease is iatrogenic heart disease. Iatrogenic means "caused by a physician." Iatrogenic heart disease is an illness in which symptoms referable to the heart, or symptoms interpreted by the patient as such, are produced as a result of the words or actions of a physician. It is of importance for the following reasons: 1. The disease produces considerable morbidity and may easily be more disabling than the average case of organic heart disease. 2. The disease should be and is preventable. 3. The treatment of the disease is specific and differs from the management of any other type of cardiac disorder.

In the American Heart Association classification, iatrogenic heart disease is listed under effort syndrome (neurocirculatory asthenia), psychoneurosis, or both. Iatrogenic heart disease, however, has significant characteristics warranting its separation and especial emphasis. First, the cause is distinct as set by definition. While some patients may have deep-seated personality disorders, the precipitating factor in all cases is the action of the physician and many times it is the sole factor. Second, and as a natural corollary, therapy is ordinarily directed on a superficial plane, psychiatrically speaking, with emphasis on encouragement and reassurance rather than on deep psychological probing. Third, and most important, separation of the disease points up the responsibility of the physician in its production and gives hope that the physician so forewarned will be less likely to cause the disease in the future.

There are no statistics to my knowledge to indicate the frequency of this condition, but several reports suggest its magnitude and importance. Oille stated, "Almost 60% of patients who consult a cardiac specialist are suffering either from an exaggerated or wholly unnecessary anxiety about their hearts, arising from suggestion and not based on reason. . . . Most of the suggestions arise from the careless or ill-considered remarks of doctors." In a classic paper on the influence of psychic factors in cardiac disorders, Conner featured the iatrogenic cause as the most important of the four factors that may produce a cardiac neurosis. Friedman states in his monograph on functional cardiovascular disease that "Unfortunately at least 10% of the hundreds of cases seen by the author were either caused or 'fixed' by some physician." One of the finest studies made of the condition labeled by the American Heart Association as "effort syndrome (neurocirculatory asthenia)" was reported by Wood in 1941 under the designation "DaCosta's syndrome." He concluded that this is invariably a psychiatric illness, though often it is overlaid on other predisposing factors, such as family history, constitutional factors, or debilitating illness. Wood made a detailed study of 100 unselected cases and reported that "DaCosta's syndrome may be induced by the doctor or by some other person in authority or it may be self-induced. The doctor was responsible in 17 cases and was an important factor in 16 others." It is evident from these references that iatrogenic heart disease is of considerable importance in clinical practice. It is also evident that this disorder is being submerged in larger categories, whereas it should be singled out for special attention. The most recent report was from the Work Classification Unit in New York, where persons were referred because of employment difficulties attributed to heart disease. It is amazing that, out of 631 persons who were adequately studied, 175 (or 28%) were found to have no heart disease at all. The authors point out that iatrogenicity was a major factor in the disability of a substantial number of these patients.

The pathogenesis of iatrogenic heart disease is quite clear. By definition, the etiological agent is the physician. From him the patient receives the impression that he has heart disease. This may occur through direct statements or actions or indirectly by the patients' interpretation of certain words or acts of the physician. It is well-known that the common reaction of the patient on receiving a diagnosis of heart disease is fear. Persons vary in their responses, depending upon their personal make-up, their life experience, and their situational reactions. The general tendency of fear is to produce the combination of psychological and physiological manifestations commonly termed "anxiety neurosis" or "neurocirculatory asthenia." Unfortunately, the symptoms are of such nature as to suggest to the patient that they arise because of disturbed cardiac function. As a result a vicious circle is set up, consisting of anxiety-producing symptoms that in turn produce anxiety. There is seemingly no effective homeostatic mechanism at work. The very patient who is most fearful of heart disease is the one most likely to have symptoms that further fix the thought of heart disease in his mind and perpetuate his fears.

MANIFESTATIONS

In investigation of the cause of chest pain, inquiry is of the utmost importance. It is often surprisingly difficult to get a patient to outline on his body the painful area, and location alone may reveal whether a pain is or is not due to cardiac disease. For example, a pain located in an area below either nipple, i. e., between the nipple and the costal margin, is almost never of cardiac origin, whereas a transverse pain across the body below both nipples is often cardiac. Submammary pains are very common, especially in women, and are very difficult to explain. Some are root pains, because spinal movements induce them. Some may be due to cholecystitis, because at times pressure over the gallbladder area produces pain below the left nipple. In most of them, however, no clue can be found to explain their cause. These pains last for hours at a time and have no relation to effort, eating, breathing, or anything except perhaps fatigue. They certainly are not important or serious; they may come and go for 15 years or more. The second location of pains that are not due to cardiac disease is outside either nipple. A general principle regarding location is that midline or symmetrical pains across the chest are more likely to be of cardiac origin; the farther out from the midline a unilateral pain occurs, the less likely it is to be cardiac pain. When pains occur outside either nipple they are not due to cardiac disease.

Of course, not all substernal pains are of cardiac origin. Some are spondylitic. Root pains in spinal arthritis may be located anywhere below the chin. Another clue may be found on inquiry about location, namely, that they shift. They occur in multiple areas and these areas change from time to time, in months or years. One must always keep asking "Where else does the pain occur?" because the last of several pains to be mentioned might be angina.

Shooting or stabbing pains are a common complaint, and in my opinion momentary sharp stabs of pain are never cardiac. They may appear repeatedly in the same location or may be felt in several different locations. They may occur as isolated stabs or as a series of sharp jabs. Especially when they are located somewhere over the left anterior chest or axilla, they not infrequently make the patient feel concern regarding his heart. Certainly angina is never a shooting or a stabbing pain that lasts for only a few seconds. Angina is a wave of distress. It begins slightly at first, increases to a maximum, stays the same for a variable time, then dies down gradually. It is extremely difficult to establish a cause for this form of distress. It occurs most commonly in persons with spondylitis and appears with certain types of work movements, or it is related to posture, such as sitting at a desk or lying in bed. It may be present in persons with almost any form of disease, but it is also frequently found in persons in whom no functional or anatomical disorder can be found.

The pain of spondylitis is usually unilateral but occasionally occurs in the midline or bilaterally and is characterized by its variability. It changes in character in the same person at different periods, from a burning to a pressure to an ache or sharp stab. It lasts any length of time, from a second to several days or even months. It occurs in different places in the chest from time to time, as well as in other parts of the body. It is these variations in character, duration, and situation that distinguish it from angina. A patient with angina has the distress in the same situation, of the same character, and for the same duration on each occasion. Spondylitic and skeletal pains are frequently worse in bed or other special postures and are often induced by some special movement rather than the degree of exertion. They may be localized to a very small area, or they may involve one-half of the chest. They spread to different parts of the chest and arms in a most unaccountable fashion. They may follow the direction of the interspaces or go directly across the interspaces and have no apparent relation to the nerve segments. Another characteristic of these pains is that they are periodic and may be absent for weeks or months at a time only to recur at some future date. Sometimes root pains are very definitely constant in character, and their localization does not shift. A pain due to root neuritis that is well localized and constant in character and radiation strongly suggests that the cause is a local lesion such as a tumor or an extruded intervertebral disk. On the other hand, most of the discomforts attributed to root neuritis are due to osteoarthritis of the spine. This process is usually fairly widespread, producing more diffuse symptoms that tend to vary in character, paralleling the natural exacerbations and remissions of this disease.

Many patients and physicians think that a pain down the left arm or both arms means the pain is due to cardiac disease. This is far from true. Most pains starting on the left side of the chest and going down the left arm are not cardiac but skeletal in origin. However, radiation down the arm, or arms, is of extreme importance when there is also a pain across the epigastrium, which could be due either to some disease below the diaphragm or to coronary disease. If it goes down the arm, it is not of gastric or gallbladder origin and is nearly always cardiac, with the exception of pain due to hiatus hernia. Pains of this origin have been noted radiating down to the elbows. Chest pain radiating to the neck and jaw or teeth is almost always cardiac. Localized tenderness is of some value as a differential sign. Hyperesthesia occurs with the pain of angina, but persists only the few minutes that the pain lasts. It also occurs with the pain of coronary thrombosis but lasts only a few days, never months or years as occurs very frequently in the case of root pain.

Some patients with neurotic pains say that walking brings them on. In such a case, it should be determined whether there is any regularity in the amount of effort required to induce the pain; angina requires an approximately fixed degree of exertion and time to be induced. In a case of noncardiac pain simulating angina, it will be found likely that some days the pain comes as soon as the patient starts to walk and that on a good day he can walk any distance without pain. Next, the constancy with which the pain occurs should be ascertained. Does it occur every time he walks the same distance at the same rate? Arthritic or neurotic pains do not occur with a regular amount of exercise and with the constancy that angina does.

DIAGNOSIS

Diagnosis is based on three criteria: 1. The patient must have symptoms. 2. The symptoms must be due to fear of heart disease, brought about by the words or acts of the physician. 3. The heart itself must be normal, though there may be a questionable or equivocal symptoms or findings. Indeed persons with equivocal findings that lead to the erroneous impression of heart disease will perhaps constitute the majority. Among these are the persons with innocent murmurs, minor electrocardiographic variations, unimportant blood pressure fluctuations, and benign arrhythmias. Then too, there is a large group of persons with normal cardiovascular findings but with cardiac-like symptoms of noncardiac origin. This group includes among others those with thoracic pain of gastrointestinal or nerve root origin and, importantly, those whose original symptoms are due to anxiety neurosis.

TREATMENT

Successful treatment depends on successful reassurance of the patient. To this end it is necessary that the physician undertaking this treatment conduct an examination sufficiently exhaustive to convince himself and perhaps even more, the patient, that the heart is sound. This is one time when the use of all the supplementary tools of cardiovascular study can be encouraged, because of the extra authenticity it lends to the examiner's pronouncements. The treating physician has a factor in his favor if the patient originally considers him to be a higher authority than the physician who provoked the fear of heart disease. In the absence of such prestige, however, an efficient, thorough examination will go a long way toward impressing the patient that the final diagnosis is based on a firm foundation. The reassurance to be effective must be clear cut. There can be no hedging. Alvarez states, "A physician is never going to cure neurosis unless he is positive when he says that the examinations showed nothing wrong. If he hedges and straddles and tries to keep a line of retreat open in case things go wrong, the worried patient will never be cured." As far as possible the differing medical opinions the patient has received should be reconciled, not only because it is tactful but also because it may make the patient's acceptance more likely. There are times, however, when such reconciliation cannot possibly be made but the physician must bluntly and firmly disagree with the pronouncements of a previous medical attendant. Under such circumstances there is no other course to follow, because the first concern must be the patient's health.

Along with emphatic reassurance as to the soundness of his heart, the patient should be made to understand how his symptoms have resulted from his fears. The simple admonition "It's all in your head" or "It's just your nerves" is entirely inadequate. As a matter of fact, it is often worse than useless, actually serving to make the patient refractory to further suggestion, since he is apt to feel that such a statement implies low intelligence, weak will power, nonexistent symptoms, or even willful malingering. I have a notion that the patient is entitled to such an attitude, for the practitioner who brushes him off in that manner is actually likely to feel just that way about the neuroses. The physician must first of all accept, and convince the patient that he accepts, the symptoms as being real. Then he must point out to the patient that the symptoms are caused not by any disease of the heart but by fear. The physician should explain briefly or fully, according to the intellectual capacity of the individual patient, the mechanisms whereby fear can produce the symptoms he experiences. The patient must be made to know that his symptoms are not dangerous to life, regardless of how distressing they may be subjectively. He should know that the symptoms will leave if his fears are relieved but may persist if he retains any fear at either a conscious or a subconscious level. It is important that he be instructed to carry on in spite of his symptoms, should they occur. Any attempt at compromise, as by instruction to "take things easy," or by giving a "little heart tonic," may be disastrous by negating the assurances of cardiac soundness. There are times when the patient must be unqualifiedly assured that his heart is absolutely normal when actually there may be slight doubts in the mind of the physician and, incidentally, in the private records. If kept there, the doubts will not harm the patient, but if they are transmitted to him, they may well defeat all the therapeutic efforts.

PREVENTION

Prevention is the most important aspect of the entire problem, since iatrogenic heart disease is potentially 100% preventable. Probably the most fruitful approach is to analyze the various reasons why the physician erroneously makes the patient feel that heart disease is present, since recognition of each reason will automatically suggest its remedy. There are five possible initiating factors: (1) misinterpretation by the patient of innocuous statements; (2) ill-considered remarks of the physician; (3) ill-considered acts of the physician; (4) error by the physician in interpreting symptoms; and (5) error by the physician in interpreting findings.

1. The problem of the patient's misinterpretation is common to every phase of medicine. An earnest practitioner may say to a patient that his heart rate is slow, his heart is small, or his blood pressure is low, in each case knowing that the finding is a favorable one. Not understanding this, the patient may interpret it in an unfavorable light and thereafter feel certain that the physician told him he had heart trouble. The physician who is constantly aware of this danger, however, will take pains to speak in such a way that his remarks cannot be misinterpreted. In the example cited, the careful physician would explain that the slow rate, small heart, or low blood pressure is the ideal finding that he sought and that convinced him that the heart is normal.

2. A second method by which iatrogenic heart disease can be initiated is through the ill-considered remarks of a physician. It would be merely scratching the surface to list such examples as "I never saw a worse heart than yours," "You have six months to live," or "You might have a stroke any minute." The remedy again is caution in speaking to patients. One should be immeasurably more careful to avoid making tactless statements that, even at face value, will produce unwarranted distress.

3. In the third method, the physician must be a professional careful actor under the critical scrutiny of the patient. If he listens too long or is too meticulous in the opinion of the patient, the latter may become panicky. He will think the physician has really found something seriously wrong, when actually the physician is making his best effort to do a good job. Do not advise rest for any cardiac patient unless it is indicated. Encourage the cardiac patients to perform physical activity just short of their level of tolerance as determined by their own symptoms.

4. In the fourth method, symptoms such as pain, breathlessness, palpitation, fatigue, dizziness, and fainting should not be misinterpreted. Careful analysis of these symptoms plus the entire process of history taking and examination must be thorough for detection of the significant clues to the proper diagnosis.

5. For the fifth method, the physician must have enough basic knowledge of diagnostic fundamentals. He should have relatively as much "cardiac" knowledge if he is going to diagnose heart disease as he would wish to have "surgical" knowledge if he were going to open the abdomen. It is certainly tragic to impose needless restrictions on cardiac patients.

918 Las Olas Blvd.

Protecting the Worker.—Whatever method is used to obtain quantitative data on the conditions of workers exposed to chemicals, it should lead to frequent observation of each worker by the plant physician who will be able to see when the workers are failing in health. By frequent contact with the men, and particularly contact on the job, he will gain their confidence. This will have two results: Not only will the morale of the individual worker be raised, but he will tend to come to the physician and to tell him of factors in both his industrial life and in his home life which may be of the utmost importance in controlling the health in the plant. In these days of a 40-hour workweek, only the smaller fraction of a worker's life is spent in the plant. That part spent out of the plant is at least as important in conditioning the worker's total health and his ability to resist hazards from chemicals as is that part spent in the plant. Any procedure that will help the physician to gather information about the total life of the worker is essential to a satisfactory program of conservation of health. In industry we are studying the whole man. Data from clinical study of sick people are not necessarily directly applicable to the healthy worker. Treatment of infections has so advanced in recent years that diseases of stress are assuming greater importance than diseases caused by bacteria or poisoning. Such diseases are due to our attempt to live with our environment, often with an environment which we ourselves manufacture. In the study of the basic factors entering into degenerative diseases, industrial medicine conducted in the manner I have suggested is at the forefront of medical research.—John H. Foulger, M.D., Physiologic Effects of Certain Explosives and Chlorinated Hydrocarbon Solvents, *United States Armed Forces Medical Journal,* October, 1953.

CHRONIC PROSTATITIS, A UROLOGIC QUANDARY

Kenneth O. Ghormley, M.D., Edward N. Cook, M.D
and
Gerald M. Needham, Ph.D., Rochester, Minn.

Although prostatitis has been recognized for more than a century, little change in therapeutic methods has been made in the past 50 years. In 1893, Fenwick reported good results with measures such as cold enemas, blistering, tonics, sitz baths, and so forth. More enthusiastic reports of current forms of treatment have been rare. The explanation of this is not clear. Chronic prostatitis is often refractory to the best of modern methods of treatment. All too often patients, suddenly aware of their prostatitis, become prostatic cripples through injudicious, prolonged, and unsatisfactory therapy. In spite of the mass of literature on the subject, too little is known about the process. Treatment often becomes stereotyped. Sir Henry Thompson, in 1860, listed certain causes of chronic prostatitis and, with minor variations, these have persisted in medical literature.

Suspecting that all prostatitis is not the same, we collected a series of cases of chronic prostatitis. Each patient was examined from many aspects in the hope of uncovering further information regarding etiological factors and the true significance of the condition. We hoped, also, to perfect a method of study that would help determine which patients require treatment and the type of treatment most likely to succeed for each.

MATERIALS AND METHODS

The patients were essentially unselected; the only requirement was that a minimum of 20 pus cells per average high-power microscopic field be found on two examinations of prostatic secretion. Consequently 105 patients, who were seen over a five month period, were studied.

All patients were referred to the section of urology from other departments of the clinic for a "prostate check." The group included patients with a history of prostatitis, fertility problems, unexplained pyuria, and symptoms suggestive of prostatitis, and patients who were examined at their own request or were sent for investigation of the prostate as a source of focal infection. A complete urologic history was taken, and the genitalia and prostate were carefully examined. Studies of the urine were made along with microscopic analysis of the prostatic secretion. This investigation took place on two successive days, and each patient was seen by at least two physicians.

Clinical Study.—In many instances, the record covered general and prostatic examinations over a period of 20 to 30 years. Because we believe that chronic prostatitis is a poorly defined entity, extensive study of clinical features was made in the hope of finding a common denominator that would not only correlate the cases but also determine some of the etiological factors.

Bacteriological Study.—As has been indicated, a diagnosis of chronic prostatitis was established first by finding an excessive number of leukocytes in the prostatic secretion. Then the bacteriological investigation was undertaken. The complete results of this portion of the study will be reported at a later date. For collection of prostatic secretion for culture, a routine procedure was adopted. 1. On a day following the first examination, a secondglass urinary specimen was collected for culture. Blood agar and eosin-methylene blue plates were inoculated with this urine. 2. The glans penis was then cleansed with 50% alcohol, the meatus compressed between sterile pieces of gauze, and the prostate thoroughly massaged. 3. Releasing pressure on the glans, the secretion was collected in a sterile test tube for culture. (Blood agar, eosin-methylene blue, and two anaerobic broths were employed as mediums.) 4. A final drop of secretion at the meatus was placed on a glass slide, with coverslip, and was studied as a wet smear under a high-power lens. The secretion was graded 2, 3, or 4, according to the number of pus cells observed in the average field. 5. The drop of secretion was then smeared over the slide by means of the glass coverslip and was allowed to dry. After it had remained in equal parts of ether and 95% alcohol for one hour, it was stained by Gram's method and was examined under an oil-immersion lens. Although the procedure entailed many steps, the results were often enlightening.

RESULTS OF THE CLINICAL STUDY

Age.—Chronic prostatitis may be found at any age after puberty. The influence of age is shown in this series of 105 cases, in which 85% of the patients were more than 40 years of age. We have always been reluctant to apply massage to the prostate of an elderly patient or to a hypertrophied prostate. In spite of the fact that this reluctance caused a number of elderly men to be excluded from the study, 19% of the patients were 60 years of age or older. Only 4% of the prostatitis in this series occurred in men who were less than 30 years of age.

History of Prostatitis.—To conclude that prostatitis is primarily a disease of the middle aged or the elderly, nevertheless, would be erroneous. Almost 60% (61 patients) gave histories of prostatitis, diagnosed either at this clinic or elsewhere. Twenty-four of these had been aware of this condition for 10 years or more. The longest history of chronic prostatitis was 33 years, but five patients had been treated intermittently for approximately 30 years. Eight years was the average duration for the 61 patients who gave histories of prostatitis. A diagnosis of prostatitis had not been made prior to this examination for the remaining 40%.

Summary of Treatment.—Most of the patients who gave histories of prostatitis had received treatment.

Fellow in Urology, Mayo Foundation (Dr. Ghormley), from the Section of Urology (Dr. Cook) and the Section of Bacteriology (Dr. Needham), Mayo Clinic.

This paper is based on a thesis submitted by Dr. Ghormley to the faculty of the University of Minnesota in partial fulfillment of the requirements for the degree of master of science in urology.

Intermittent courses of massage were used more than other methods of treatment and had been given to 80% of this group for varying periods of time. Thirty-three per cent had received chemotherapy for their prostatitis, while 25% were treated with urethral instillations and local medication. The use of urethral sounds was recorded in only 10% of the cases. Surgical procedures were rare. Two patients gave histories of vasectomy, and there was one instance each of epididymectomy, urethral cauterization, and transurethral resection of the prostate.

History of Gonorrhea.—Forty of the 105 patients in this series admitted having had at least one gonorrheal infection (38%). A smaller percentage of this group reported multiple attacks; one patient claimed he had been infected 8 or 10 times.

Symptoms in Group of Patients with Prostatitis

Symptoms	No. of Patients
Asymptomatic	24
Lower urinary tract	
Dysuria	23
Urethral discharge	21
Frequency	14
Poor stream	9
Nocturia	7
Hesitancy	4
Pain (all varieties and locations)	
Perineal	13
Low back	11
Arthritic	6
Low abdominal	6
Penile	6
Rectal discomfort	5
Generalized backache	5
Joint and muscle	4
Testicular	4
Ejaculation	1
Neurotic manifestations	
Tension state	5
Hypochondria	5
Impotence	3
Sexual fixation	1
Genitourinary bleeding	
Hematuria	4
Hematospermia	1
Miscellaneous	
History of pyuria	12
Chills and fever	5
Recent epididymitis	3
History of prostatic calculi	3
History of trichomonas	2

Findings on Digital Examination.—Rectal examination of the prostate was not diagnostically helpful in this study. In every instance, the prostate was examined digitally and was evaluated according to size, consistency, and the patient's sensation. Enlargement was graded 1 to 4. A prostate of grade 1 enlargement was considered to be of nearly normal size and of no particular pathological or clinical significance. In 85% of cases, the prostate was considered either of normal size or minimally enlarged. Thirteen per cent of the prostates showed moderate hypertrophy; none were judged larger than grade 2.

Fifty-five per cent of the prostates of this series were considered to be of normal consistency. Twenty-eight per cent were described as "boggy" and the remaining 17% as "firm." Seventeen per cent of the patients were believed to show evidence of increased prostatic sensitivity. Rectal examination is uncomfortable, however, and the patient is likely to wince. Except in extreme cases, therefore, the significance of the patient's sensation seems questionable.

Grade of Prostatitis.—All patients in this series had prostatitis of grade 2, 3, or 4. The prostatic secretion was studied microscopically under the high-power magnification, and the following estimate was used: Normal, 0 to 6 pus cells per high-power field; grade 1, 7 to 20 pus cells per high-power field; grade 2, 21 to 50 pus cells per high-power field; grade 3, approximately three-quarters of an average high-power field occupied by pus cells; and grade 4, average high-power field solidly packed. According to this scale, in 45% of cases, prostatitis was interpreted as grade 2; in 27%, as grade 3, and in 28%, as grade 4. This evaluation was relatively accurate because the secretion was examined on at least two occasions in the course of the examination.

Association of Prostatitis with Pyuria.—Pyuria might be anticipated in the presence of large amounts of purulent secretion in the prostate. The routine morning specimen was examined prior to prostatic massage. The following system of grading was employed to estimate the degree of pyuria in a sample of centrifuged urinary sediment: Negative, no pus cells; occasional, 1 to 3 pus cells per high-power field; pus grade 1, 4 to 20 pus cells per high-power field; pus grade 2, 20 to 50 pus cells per high-power field; pus grade 3, three-fourths of average high-power field occupied; and pus grade 4, average high-power field packed. In 35% of 101 cases, smears of the urine were negative or contained only an occasional pus cell. Pus was of grade 1 in 39% of cases, grade 2 in 19%, grade 3 in 7%, and grade 4 in only 1 case.

There was little correlation between the degree of pyuria and the degree of prostatitis. Of the 101 patients, the 55 with grades 3 and 4 prostatitis were variable with respect to pyuria. In 58% of this group, the urine was essentially normal, or pyuria was mild or grade 1. Only 11% of the patients had grade 3 pyuria.

Symptomatology.—Textbooks are vague concerning the symptomatology of chronic prostatitis. No characteristic pattern of symptoms could be found in this group of patients. A list of 27 different symptoms or pertinent findings was compiled from the histories. Many patients had multiple symptoms, some had only one symptom. The largest single group was asymptomatic. In an effort to achieve some semblance of order, the symptoms were broken up into classes. These are listed, together with the number of patients who gave histories of each complaint, in the table.

No correlation could be found between the grade of prostatitis and the presence or extent of symptoms. Frequently a patient with mild prostatitis had multiple symptoms, while one with severe prostatitis was asymptomatic. Although the preponderance of patients with many symptoms had received considerable treatment for their prostatitis, there was an appreciable number with few or no symptoms who had received extensive therapy over many years. No psychiatric evaluation of the patients in this series was attempted. Many of those with the most exaggerated symptoms, however, showed a considerable element of psychoneurosis. Bizarre symptoms of these patients multiplied with therapy, and their concern grew with each prostatic massage.

RESULTS OF BACTERIOLOGICAL STUDY

As has been said, a detailed report of the results of this study will be published at a later date. Several observations were made, however, that are of general interest. Although an extensive bacteriological investigation would be impracticable in every case of prostatitis, there are instances in which it is a decided advantage to have this information. By means of cultures of the prostatic secretion and urine and smears of each secretion stained with Gram's stain, the data comprising this important portion of the study were assembled.

Bacteria Isolated from Prostatic Secretion.—Of the 105 patients in this series, bacteria were recovered on culture of prostatic secretion of 91.5%; there was no growth on any medium from the prostatic secretion of 8.5%. Contrary to several reports, mixed flora were frequently encountered in our series.

On the basis of usual clinical experience, the bacteria were arbitrarily divided into three groups: recognized pathogens, nonpathogenic bacteria, and a small, miscellaneous group that might be considered pathogenic. The pathogenic bacteria included Escherichia coli, Streptococcus faecalis, Aerobacter aerogenes, Pseudomonas aeruginosa, and Micrococcus pyogenes. The nonpathogenic bacteria included Micrococcus (species undetermined), alpha hemolytic Streptococcus, Corynebacterium, and nonhemolytic Streptococcus. The miscellaneous group included anaerobic and rare species of bacteria.

Only 36% of the total number of bacteria cultured were pathogenic, while 60% were nonpathogenic. The bacteria most frequently found were nonpathogenic micrococci; these accounted for 40% of the total bacteria identified, or 69% of the nonpathogenic group.

Bacteria Isolated from Urine.—The urine of all but two patients of this series was cultured. Cultures of the urine of 34% of the patients gave positive results, while those of 66% gave no growth. The bacteria also were divided into pathogenic and nonpathogenic groups. Sixty-three per cent were classified as pathogenic, while only 37% were considered nonpathogenic.

After studying individual cases, it was discovered that, while 60% of the pathogens cultured from the prostatic secretion were also cultured from the urine, only 15% of the nonpathogenic prostatic bacteria were present in the urine. In order to determine the clinical significance of a pathogenic organism found in both the prostatic secretion and the urine, the symptoms of the 25 patients with both prostatic and urinary pathogens were reviewed. Of this group, 64% complained of either dysuria or a recent genitourinary infection (for instance, acute epididymitis). Whether the prostate became involved primarily or secondarily could not be determined.

Prostatic Secretions with Negative Cultures.—Cultures of the prostatic secretion of nine patients in this series were bacteriologically negative. The degree of involvement was variable, with an equal number having prostatitis of grade 2, grade 3 and grade 4 on the basis of examination of a wet smear. Culture of the urine of all nine patients gave no positive results. The symptomatology was complex and showed no correlation. Although four of the patients were asymptomatic, several of the worst problems, psychologically and otherwise, were encountered in this group. Five of the nine patients gave evidence of an anxiety state or of severe psychoneurosis. Two patients had received chemotherapy not long before the prostatic examination for symptoms suggestive of acute inflammation of the lower part of the urinary tract. It is appreciated that bacteria might well have been present prior to this treatment.

Gram-Stained Smears.—Smears of all prostatic secretions were stained with Gram's stain. These smears were studied independently, without knowledge of the flora obtained on culture. This examination was thorough, time-consuming and, no doubt, overzealous on occasion. In most cases, results of examination of the smears were unequivocally positive or negative, and the bacterial types were easily recognized. Results of examination of 20% of the smears significantly disagreed with the results of culture. The source of this error was not always apparent. In some instances, however, the smear seemed more informative than the culture.

Pathogenic Prostatic Bacteria with Negative Culture of Urine.—True "bacterial prostatitis" could be assumed to be present if a patient's prostatic secretion gave a positive culture but his urine a negative one. Only 13 patients had pathogenic organisms in the prostatic secretion and also passed urine from which no growth could be obtained. They represented all grades of prostatitis and a variety of bacteria. Some were asymptomatic, but the remainder had a wide variety of symptoms, seemingly unrelated. Esch. coli were found in the prostatic secretion of two patients with histories of intermittent dysuria.

Infestation with Trichomonas.—Apparently only 104 cases of infection with Trichomonas vaginalis in the male had been reported by 1938. In 1944, however, Roth demonstrated this to be a common venereal infection of Negro men. Six cases of infestation with Trichomonas were encountered in this investigation. All of these patients were white, and the protozoans were present in the urine. Organisms were seen in the prostatic secretion of three of these men.

Pleuropneumonia-like Organisms.—At the conclusion of the bacteriological study, the prostatic secretions of 25 additional patients with prostatitis were cultured for pleuropneumonia-like organisms. Although some cultures were not satisfactory because of overgrowth of various bacteria, three positive cultures were obtained.

COMMENT

The primary purpose of this investigation has been to survey many aspects of chronic prostatitis in order to determine what may be the causative factors. To accomplish this, 105 patients were carefully studied. The data collected fell into two categories, clinical features and a bacteriological study. It readily became apparent that a simple, concise definition of the etiology of prostatitis was not feasible. Although chronic prostatitis frequently is spoken of as a "disease," no pattern of symptoms is characteristic, and most cases have little in common. Consequently, generalizations as to etiology, symptomatology, prognosis, or treatment seem not only misleading but superfluous. Reduced to simplest terms, prostatitis is an inflammation of the prostate gland characterized by an excessive number of leukocytes in the prostatic secretion. The finding of pus cells in the prostatic secretion was the only characteristic all patients had in common. Etiological factors of chronic prostatitis should be found in the sources of this inflammation.

The majority of patients in this series were more than 40 years of age. Age, therefore, seems to be a factor in the incidence of prostatitis. This can be explained in several ways. A large number of middle-aged or elderly men had a history of prostatitis of many years' duration. Added years provide patients with an extended opportunity for exposure to agents that cause prostatitis or to the physician's finding it. The diminishing sexual activity of increasing age may be of some significance. Likewise, structural changes in the prostate, which accompany benign hypertrophy, undoubtedly interfere with normal function of the gland. Age may make the prostate increasingly vulnerable to prostatitis.

The role of gonorrhea in the etiology of prostatitis frequently has been stressed. Only 38% of the patients in our series admitted previous gonorrheal infection. The urethral trauma incident to former methods of treatment no longer occurs. With chemotherapy available, prostatitis should be seen much less often as a sequel of gonorrhea.

Laboratory study of prostatitis has been limited, in large part, to cultural, serological, and immunological investigations. Because of the trend of this research, chronic prostatitis has been primarily regarded as a bacterial inflammation. Unlike other bacterial infections, the results of chemotherapy have been disappointing. The relationship of bacteria to prostatitis is not clear. In the present study we have tried to broaden the scope of the bacteriological investigation in an attempt to demonstrate this relationship.

More than 90% of the secretions cultured were bacteriologically positive. Of the bacteria recovered, 36% were recognized pathogens, while 60% were bacteria usually considered to be nonpathogenic. Compared to the high percentage of positive prostatic cultures, 33% of the patients had positive urinary cultures. Only 15% of the large group of nonpathogenic prostatic bacteria were recovered from the urine, while, in striking contrast, 60% of the prostatic pathogens were found on culture of the urine. Two-thirds of those with pathogenic organisms in both prostatic secretion and urine gave histories of dysuria or a recent genitourinary infection in addition to their prostatitis. Bacteria may well play an important causative role in this group of patients, and trial of chemotherapy would seem indicated notwithstanding the current disappointing reports of such treatment.

Cultures of prostatic secretion and urine of nine patients in this series gave bacteriologically negative results. They represented all degrees of prostatitis and they had a wide variety of symptoms. More than a third of the positive prostatic cultures were bacteriologically insignificant and presumably were attributable to contamination. With this large group in mind, it was our impression that chronic prostatitis is not always attributable to bacterial infection. Amicrobic prostatitis may well explain past failures of chemotherapy.

CONCLUSIONS

The quandary of chronic prostatitis is difficult to resolve. Although the diagnosis is easily made, there are no characteristic physical findings or symptoms. Treatment, while stereotyped, is frequently unsatisfactory. Chronic prostatitis is widespread and too often becomes an obsession of the hypochrondriac. As encountered, the prostatic cripple is the product of injudicious and prolonged therapy. All prostatitis is not the same and its significance is variable. A more critical approach to the individual case will prove beneficial, not only to the patient but to his physician as well.

CLINICAL NOTES

NEPHROTIC SYNDROME OCCURRING DURING PARAMETHADIONE THERAPY

REPORT OF A CASE WITH CLINICAL REMISSION

James C. Wren, M.D.
and
Robert L. Nutt, M.D., Englewood, N. J.

Three cases of a nephrotic-like syndrome appearing in patients taking trimethadione (Tridione) have been reported. In May, 1948, Barnett and associates[1] reported the case of a 16-year-old girl who had been taking trimethadione for eight months when massive edema, 4+ proteinuria, hypoproteinemia, and hypercholesterolemia appeared but results of renal function tests were normal. In this case nephrosis occurred two additional times, both following further courses of the drug.

In February, 1949, White[2] reported a similar case in which a 20-year-old man in whom massive edema, 4+ proteinuria, hypoproteinemia, and hypercholesterolemia developed following a 10 month course of trimethadione. As in the case of Barnett and co-workers,[1] the edema, proteinuria, and abnormal blood chemistry reverted to normal within six weeks after withdrawal of the drug.

Briggs and Emery[3] reported a case in which a nephrotic syndrome developed after trimethadione therapy for four months. This child did not have a clinical remission after withdrawal of the drug. The child died eighth months after the onset of the nephrosis. Abbott and Schwab[4] thought this might have been a case of chronic glomerulonephritis.

Davis and Lennox[5] attributed a case of nephrosis to paramethadione (Paradione). This case was not reported

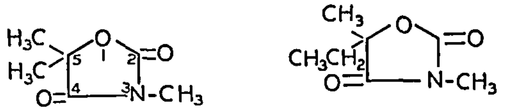
in any detail, only alluded to, so to date no fully documented case of a nephrotic syndrome appearing in a patient receiving paramethadione has been reported. It is easily conceivable that a drug so closely related to trimethadione as paramethadione could also produce a toxic nephrosis. The diagrams show the close structural relationship of the two drugs.



TRIMETHADIONE PARAMETHADIONE

Structural formulas of trimethadione (Triodone) and paramethadione (Paradione).

REPORT OF CASE

A 26-year-old white man was admitted to Englewood Hospital on Oct. 2, 1952, with marked swelling of both lower extremities, scrotum, penis, hands, forearms, and face. The patient began to have dizzy spells two to three times a week at the age of 16. In 1944, when 18 years old, he entered the Army and, as he stated, "started having blackouts." He would drop to the floor, had no aura, did not soil or injure himself during an attack, and was not sleepy after attacks. These spells occurred daily while he was in basic training but later he experienced them only two to three times a month. Because of the seizures he received a medical discharge.

In November, 1946, because of increasing frequency of these seizures, he consulted a neurologist who made the diagnosis of idiopathic epilepsy with grand and petit mal features. The patient was given 0.3 gm. of trimethadione and 0.015 gm. of phenobarbital four times per day. This dosage was maintained through June, 1949, when the trimethadione therapy was discontinued and administration of diphenylhydantoin (Dilantin) sodium started with phenobarbital. In April, 1951, following a change in physicians, he was placed on a dosage schedule of 1.5 gm. of paramethadione and Mesantoin (3-methyl-5,5-phenylethylhydantoin) 0.5 gm. per day both in divided doses. On these drugs he had only one to two seizures per month.

In late September, 1952, while still receiving the same doses of paramethadione and Mesantoin, he noted tightness of his shoes and watchband, plus swelling of his face. He became alarmed as the swelling progressed, and he consulted a local physician. The physician found generalized pitting edema with albuminuria and advised hospitalization. The patient had no past history or symptoms pointing to abnormalities of his cardiovascular, renal, or gastrointestinal systems. No other members of his family were known to have had convulsive disorders or kidney disease.

Physical examination on admission revealed a well-developed young man with obvious body swelling. He weighed 186 lb. (84 kg.), although his usual weight was 150 lb. (68 kg.). The pulse rate was regular at 80 per minute and respiration at 18 per minute. The blood pressure was 112 systolic and 68 diastolic. His face was pale and puffy. The ocular fundi appeared normal. The lungs were clear to percussion and auscultation. No cardiac enlargement was noted. His abdomen was protuberant, with a fluid wave and shifting dullness. There was 3+ pitting edema of the feet, legs, thighs, and forearms.

The hemogram on admission showed 5 million red blood cells, with 14.4 gm. of hemoglobin per 100 cc. There were 9,100 white blood cells with 69% segmented polymorphonuclear leukocytes, 1% eosinophils, and 30% lymphocytes. The Kline reaction was negative, the hematocrit 51%, and the erythrocyte sedimentation rate 34 mm. in one hour (Wintrobe). Urinalysis revealed light amber urine with a specific gravity of 1.024, 4+ albuminuria, and no sugar. Microscopic examination of the urine showed 3 white blood cells per high power field, no red blood cells, and an occasional finely granular cast. Blood chemistry studies on admission showed 4.54 gm. of total serum protein per 100 cc., with 1.59 gm. of serum albumin and 2.95 gm. of serum globulin. The albumin-globulin ratio was 0.6:1.0, the nonprotein nitrogen level 32.4 mg., creatinine level 1.5 mg., the cholesterol level 478 mg., and cholesterol esters level 196 mg. The chloride, sodium, and potassium levels were all within the range of normal. The results of a urea clearance, phenosulphonphthalein dye excretion, and Fishberg concentration tests were also within limits of normal. The basal metabolic rate was -34. The chest roentgenogram and flat film of the abdomen revealed nothing remarkable.

The patient was placed on a low salt diet and continued on his antiepileptic regimen of Mesantoin and paramethadione while the diagnostic work-up was being completed. A review of the literature revealed the above mentioned toxic nephrotic-like syndrome occurring with trimethadione, so on the fifth hospital day administration of paramethadione was discontinued, while Mesantoin and phenobarbital therapy was maintained.

The following day cortisone therapy was started. He was given 200 mg. per day for three days, followed by 100 mg. per day for seven days. No diuresis occurred. The patient's weight remained 186 lb. (84 kg.) after the 10 day course of cortisone. Starting on the 11th day after administration of paramethadione had been stopped, the urinary output increased. A high urinary output, varying between 1,500 to 3,500 cc. per day, lasted 15 days. At the end of this time, 25 days after paramethadione was discontinued, the patient was free of edema and weighed 149 lb. (67.4 kg.). On the 34th hospital day he was discharged to be followed in the outpatient clinic. At this time his urine showed 1+ albuminuria. The total serum protein level had risen to 5.21 gm. per 100 cc., with 2.65 gm. of serum albumin, and 2.60 gm. of serum globulin; thus the albumin-globulin ratio was 1:1. The cholesterol value was still elevated at 515 mg.

The patient was asymptomatic at clinic visits over the next five months. His weight remained around 150 lb. (68 kg.), with normal pulse, temperature, and blood pressure. Repeated urinalysis showed a steady diminution in the albuminuria. The urine contained no albumin six weeks after the paramethadione therapy had been discontinued and at the time of writing, March 28, 1953. Ten weeks after administration of the drug was stopped, the total serum protein content was 5.45 gm. per 100 cc., with 2.94 gm. of serum albumin and 2.51 gm. of serum globulin. The albumin-globulin ratio was 1.05:1.0. The serum cholesterol level had fallen to 212 mg. per 100 cc. Three months after paramethadione therapy was discontinued, the serum protein level, the albumin-globulin ratio, and serum cholesterol level were all within the normal range, and were also normal on March 28, 1953. The patient now receives Mesantoin and phenobarbital.

COMMENT

In this case the patient had been receiving trimethadione for two and one-half years with no apparent toxic effects but after one and one-half years of paramethadione therapy began to manifest a nephrotic-like syndrome. As in the reported cases of a nephrotic-like syndrome occurring in patients receiving trimethadione, our patient also had normal renal function tests. The diuresis that began 10 days after paramethadione therapy was stopped and continued for 17 days also parallels the events in the trimethadione cases. Although the results of urine tests returned to normal within six weeks, as occurred in Barnett's [1] case, the serum protein and cholesterol levels in our case were a little slower in returning to normal.

The effect of cortisone on the diuresis is open to question. Workers[6] who have employed cortisone and/or corticotropin in the nephrotic syndrome found corticotropin to be much more effective in producing diuresis. Cortisone seldom produced diuresis. In the nephrotic stage of chronic glomerulonephritis treated with cortisone, any diuresis usually begins on the 7th to 10th day of therapy. The diuresis lasts only three to five days. In this case diuresis began on the 10th day of cortisone administration, the 11th day after administration of paramethadione was stopped, and continued for 17 days. This pattern of diuresis approximates that seen after withdrawal of trimethadione.[7]

To date photophobia, mild to severe dermatitides, drowsiness, nausea, hepatitis, agranulocytosis, and nephrosis have been reported[8] to occur in patients receiving the oxazolidine-2, 4 diones (trimethadione and paramethadione). Nephrosis is a rare toxic manifestation, but it is shown by this case and the others mentioned that a urinalysis should be included in the monthly examinations of epileptics receiving trimethadione or paramethadione. Abbott[4] and Kaufman[9] recommend monthly urinalyses, including bile tests, and complete blood counts, as long as the patient is taking the drugs. This is certainly borne out by our case. Abbott[4] wisely suggests careful physical examination, urinalysis, and complete blood count before paramethadione or trimethadione therapy is begun.

SUMMARY

A case of nephrosis occurring during paramethadione (Paradione) therapy is described. The nephrotic-like syndrome cleared six weeks after discontinuance of therapy with this drug. A 10 day course of cortisone did not produce significant diuresis. The need for simple laboratory tests at monthly intervals while patients are on prolonged administration of certain of the newer antiepileptic drugs is stressed.

Physical Therapy.—Physical therapy is an auxiliary to the art and practice of medicine and should be practiced under a physician's supervision, particularly when it is the major treatment given the patient. The diagnosis must be confirmed before treatment is started with physical therapy. The measures applied must be realistic and of dynamic character, and the patient's progress should be followed by the physician and physical therapist. The physician-physical therapist relationship is one of mutual exchange of thought and leads to mutual comprehension of the therapeutic goal and the therapeutic measures necessary for its attainment.—Lieut. Col. Robert W. Augustine, The Relation of Physician and Physical Therapist, *United States Armed Forces Medical Journal*, October, 1953.

SIMPLE DEVICE FOR TRACHEOBRONCHIAL ASPIRATION

Ernest B. Emerson Jr., M.D., Rochester, N. Y.

Most physicians who perform tonsillectomy and oral surgery are well aware of the fact that occasionally, despite careful preoperative medication, mucus does develop in the tracheobronchial tree in quantities that hinder continuous insufflation anesthesia. Under certain circumstances beyond immediate control, it is possible for a patient to have his tracheobronchial tree contaminated with blood. The tracheobronchial aspirator has been designed to simplify the correction of these difficulties without removal of the gags in use, even in the absence of a trained endoscopist. The latter is especially important in view of the fact that the vast majority of surgeons performing tonsillectomy and oral surgery are not trained in endoscopy and need an adequate means of handling such situations.

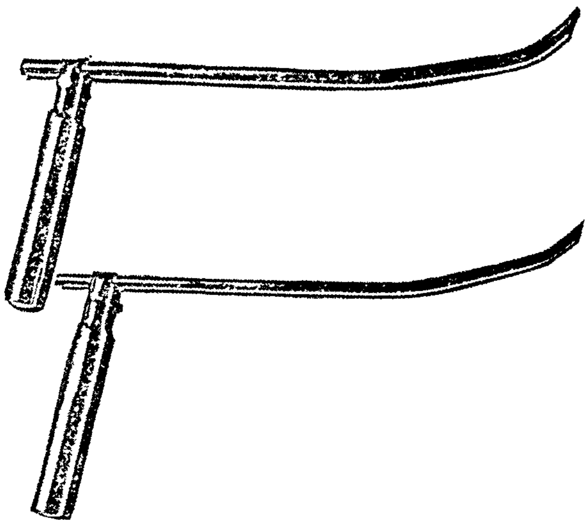

Fig. 1.—The tracheobronchial aspirator. One size is for no. 14 and the other for no. 18 French suction tube.

DESCRIPTION

The tracheobronchial aspirator (fig. 1) is a simple piece of equipment designed so that a rubber suction tube can be passed through it into the trachea with only headlight illumination and without removing the mouth gag. It consists of a removable handle and a long brass tube of such diameter that either a no. 14 or 18 French rubber suction tube may be passed through it. The carrier through which the suction tube passes is bent to allow easy access to the trachea without undue trauma while the gag is still in place.

TECHNIQUE

The technique will be self-explanatory to the endoscopist with but a glance at the diagrammatic illustration of the instrument in use (fig. 2). The steps of insertion are: (1) pass the carrier tube into the mouth and throat

---

The tracheobronchial aspirator is available through the Welch-Allyn Company, Skaneateles Falls, N. Y.

From the Department of Surgery, Division of Otolaryngology, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., and in conjunction with the Bronchoscopic Service of the Veterans Administration Hospital, Batavia, N. Y.

along the midline; (2) pick up the tip of the epiglottis; (3) lift the epiglottis up as far as possible and, at the same time, advance the instrument about a centimeter (further in adults); and (4) hold the instrument steady and rapidly pass the rubber tube, with the suction cut off, down the tracheobronchial tree. To remove the aspirator, release the suction while withdrawing the tube with deliberation.

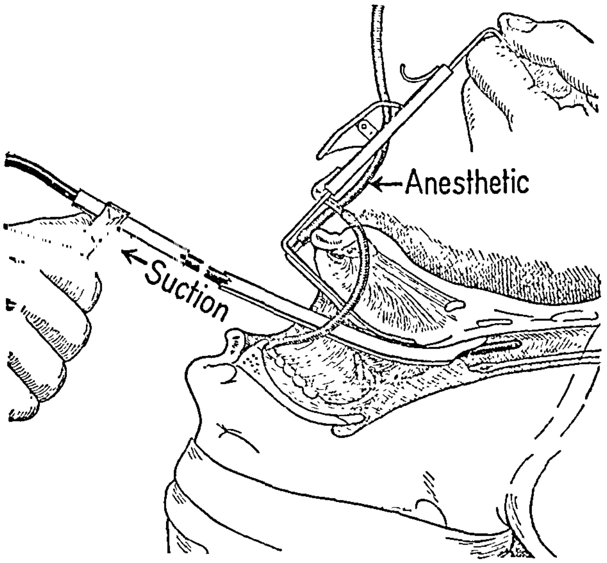

Fig. 2.—The tracheobronchial aspirator in use. Note gag has not been removed, yet entrance to trachea is relatively easy.

SUMMARY AND CONCLUSIONS

A tracheobronchial aspirator is described. The instrument has been found satisfactory for the aspiration of blood and mucus from the tracheobronchial tree during tonsillectomy or oral surgery without the inconvenience of removing the mouth gag. Satisfactory aspiration may be thus accomplished in the absence of an endoscopist.

Treatment of Carcinoma of Prostate.—The treatment of carcinoma of the prostate depends upon the extent of the neoplasm and the general condition of the patient. In those lesions limited completely to the prostate, if the general condition of the patient warrants it, radical removal of the prostate by either the perineal or retropubic route may be carried out. The retropubic technique offers more extensive exposure of the regional lymph nodes and the seminal vesicles and possibly, therefore, permits a little more radical removal of the carcinomatous area. A great deal of this, however, depends upon the experience of the surgeon. In those cases where the carcinoma has extended beyond the capsule of the prostate and is, therefore, inoperable by radical prostatectomy, interstitial radiation using radioactive isotopes, such as Au^{198}, emitting primarily beta radiation seems promising. . . . In those patients with carcinoma of the prostate where the lesion has metastasized so that the previously described methods of treatment cannot be used, the treatment is palliative and consists essentially of relief of bladder neck obstruction by transurethral resection, conservative prostatectomy or suprapubic cystostomy and endocrine control of the neoplasm by orchiectomy and estrogen administration. When the neoplasm of such patients becomes refractory to orchiectomy and estrogens and the general situation warrants it, bilateral adrenalectomy may be considered.—R. H. Flocks, M.D., Treatment of Carcinoma of the Prostate, *Transactions of the Western Section of the American Urological Association*, May, 1952.

SPECIAL ARTICLE

A PHYSICIAN AND AN ECONOMIST LOOK AT OLD-AGE AND SURVIVORS INSURANCE

F. J. L. Blasingame, M.D., Wharton, Texas
and
Frank G. Dickinson, Ph.D., Chicago

This article reflects the views of the authors and not necessarily the official policy of the American Medical Association. —Ed.

The subject of social security is particularly important to members of the medical profession. Current proposals in Washington to include self-employed physicians under the benefits of Old-Age and Survivors Insurance (OASI), as most employed physicians have been since 1950, make the question timely.

TOWNSEND PLAN

Physicians can speak out against the extension of OASI benefits without indulging in any kind of interprofessional mudslinging. One of the grandfathers of the idea of free pensions is a member of the medical profession, Dr. Francis E. Townsend. While a city health officer in Long Beach, Calif., he became famous for his pension plan before the enactment of the Social Security Act in 1935. Although there are persons today who still cling to Dr. Townsend's basic ideal, his ideas were an outgrowth of the depression years, and his plan was intended to stimulate consumption and thus to pull us out of the depression. The Townsend Recovery Plan provided that each retired person over 60 be given $200 a month to spend within the month. The funds for distribution would have been built up out of a 2% transactions tax.

A 1952 report by the then Federal Security Agency ("Social Security Financing," Bureau Report No. 17, 1952) describes contemporary Townsendism as a plan calling for a 3% tax on all gross income, excluding the first $250 per month for persons. The revenue from this tax would be distributed equally among the retired aged, the totally disabled, and widows with dependent children. No means test would be used. Supporters of this plan would use it to replace the present Old-Age and Survivors Insurance program and much public assistance.

The economic problems of such a system as this are obvious; not only benefits might vary at monthly intervals, but prices would probably rise. Most evident, however, is the moral side of this issue; the aged, disabled, and widowed would all be living on the income of others. The healthy and employed population would be turning over its potential savings to a compulsory charity with equal benefits for retired bank presidents and cleaning women and would be paying higher prices in order to do so. Obviously, contemporary Townsendism, by that name, is not the answer. We laugh at it as others laughed at Townsend and his followers less than 20 years ago. But what we fail to realize is that a twin brother to the

---

Trustee of the American Medical Association and Chairman of Committee on Legislation (Dr. Blasingame) and economist and statistician, American Medical Association (Dr. Dickinson).

Townsend plan may actually be just around the corner under the guise of social security extension. The report "Social Security Financing" recognizes these drawbacks but says that the plan may continue to have its advocates as long as the Old-Age and Survivors insurance system is less than complete in coverage. But this very effort to bring about complete coverage may actually produce a Townsend plan. Movements to extend OASI further seem definitely close at hand. Why is this, and what is the answer?

ELECTORATE IS AGING

Between 1930 and 1934, the year Dr. Townsend made his proposal, first graders had decreased from 3.3 to 2.5% of the total United States population. The older generation was staying alive and healthy, and with the birthrate on the downgrade the possibility was strong that the old would become preponderant. Since that time the number of the nation's school children has increased, as today's crowded schools testify, and children are continually having better and better chances of living through childhood diseases; likewise, the older generation is benefiting from improved medical care. Middle-aged men and women are surviving the attacks of influenza, pneumonia, and tuberculosis that were fearfully fatal to their parents and grandparents and living until they are taken by the typically "older" causes of death, like cancer and heart disease. This health progress was obvious in 1935 and is even more so now; the median age at death has risen from 30 years in 1900 to 67 today.

When the age distribution of a population changes so radically in such a short time, the shift is potentially powerful. It brings a change in the economy of a nation as places for retired living grow in size and importance. It changes and challenges society as the proportion of older persons who must be cared for and kept mentally active increases. Furthermore, such a population shift can bring about a strong change in the political balance. Since 1900 the portion of the electorate 50 years of age or older has increased from 24% to 36 or 37%. Is a shift of 12 votes in 100 important? Our political friends say it is a very large shift. The older persons, of course, retain their voting power, and simultaneously they gain more leisure time to study political issues and exert political power.

What are we doing for these persons today when we give them Old-Age and Survivors Insurance benefits? An insurance benefit is psychologically more acceptable than charity. But let us examine the facts and see just how much of the benefits of this insurance are prepaid in premiums.

Current estimates indicate that only 6 to 20% of OASI benefits being paid out today were prepaid by the beneficiaries or their employers. If you will, 80 to 94% of the cost was not prepaid by the employee and his employer before the pension started. Old Age Assistance (OAA) is 100% charity. Is it any wonder that OASI has not succeeded in displacing OAA as promised when the Social Security Act was enacted in 1935? But OAA, however, is not the subject of this paper. Cut-rate premiums were prepaid by those now drawing OASI pensions. It is like buying a $70 suit for $3.42 or $15.98. Did you pay for it? A self-employed person at age 62, for example, brought under OASI in 1951, by paying as little as $121.50 in OASI taxes could have provided a pension of $80 a month for himself, $40 a month for his wife, and $60 a month during the years that she lived after his death. An insurance company, on the other hand, would want about $23,000 at age 65 for such a contract. The difference between $121.50 and $23,000 is great—a substantial amount to receive in charity from persons in all income brackets! And the $80 and the $40 were increased to $85 and $42.50 by Congress in 1952. How much will Congress increase the benefits prior to the 1956 elections? The 1960? The percentage of older voters is increasing and the votes of the post-World War II babies will not arrest this trend for another two decades.

Because the OASI Trust Fund has a "surplus" of 18 billion dollars, the presidential advisors persuaded the President to send a special message to Congress (May, 1953) requesting postponement of the rise in OASI taxes scheduled for Jan. 1, 1954—from 1.5 to 2% by employer and employee on salaries up to $3,600. They argue that this plan is feasible because there is already enough money in the OASI Trust Fund to pay all future payments to those now receiving benefits. This "surplus" came mostly from payments by younger workers and their employers. In truth, it belongs to them. The advisors would, in effect, make it even more obvious than ever that the older workers will not make more than token payments toward their pensions. If you will, the presidential advisors are not satisfied with a system that is only 80 to 94% Townsendism. Apparently they want OASI pensions to become pure gratuities from Uncle Sam. Gratuity is a harsh word for the old; so is Townsendism for the young.

If OASI is ever to become equitable, it cannot be put on a pay-as-you-go basis—current income equals current outgo. In essence, the present OASI Trust Fund compels future congresses to appropriate funds for pensions; as a compulsory future appropriation the "reserve" assures future payments from the fund to those who have contributed toward it, but in amounts far in excess of their (and their employer's) contributions. If OASI were to be set up on a pay-as-you-go basis, concerned only with balancing annual income and outgo, future appropriations for these pensions would no longer be guaranteed by a "reserve." The aging of the electorate would seem to guarantee that Congress would honor this obligation in the future. Putting OASI on a pay-as-you-go basis would, however, continue the present inequity of forcing the young to pay currently what the old receive. We are told that it would merely mean taking money out of one pocket and putting it in another. Our answer is that the pockets would not be in the same pair of pants. What we need is equity between the young and the old, not a new fiscal policy for OASI.

But the moral side of this issue is paramount. Suppose that, regardless of the psychological effect on the older generation, we propose now to pay OASI benefits out of current revenue and to use up the "surplus" in the trust fund. In doing so we are forcing on our children the task of paying for our benefits and forcing their children to pay for theirs. We are extending indefinitely the task of paying more and more taxes for old-age support, since the burden of payment will increase as the number of persons over 65 and the length of time they live beyond 65 increase with health progress. Between 1935 and 1950 the population of the United States increased 18%, while the population 65 and over increased 57%. With beneficiaries continuing to live longer, contributors will soon pay such taxes that they will have no hope of ever saving toward retirement. This is a morally unsound state. It is like presenting a newborn baby with the obstetrician's bill. It is like trying to bring everyone's income up above the average. It puts us on a treadmill of time. We who are now past 50 rob workers under 50. If they object, we tell them to get even by robbing still younger workers.

It is much too easy to rationalize the postponement of our own payments for our children to pay, especially if the payments are labeled insurance. But so far several groups of self-employed workers have held out against being included in Old-Age and Survivors Insurance. The American Bar Association, American Dental Association, and American Farm Bureau Federation as well as the American Medical Association have gone on record as opposing the extension of OASI to self-employed farmers and professional persons. They are withstanding the pressures to leave the responsibility of their future support to their children. On behalf of their members they refuse to accept the bait: pension gifts (in installments) from Uncle Sam of $5,000, $10,000, $15,000, or $20,000, depending on the member's age and his plans for retirement.

PRESIDENT'S ADVISORS

In his State of the Union Message of Feb. 2, however, the President recommended that the "old-age and survivors insurance law should promptly be extended to cover millions of citizens who have been left out of the social security system." On Aug. 1 he recommended to the Congress an extension of coverage based on a report filed with the Secretary of Health, Education, and Welfare by a group of consultants on social security. Their plan suggests that coverage be extended to cover about 10 million more workers. In addition to the state and local government workers, farmers and domestic workers, ministers, home workers, and others who would thus be covered by OASI there are about half a million self-employed professional persons who would be covered for the first time: accountants, architects, chiropractors, Christian Science practitioners, dentists, funeral directors, lawyers, naturopaths, optometrists, osteopaths, physicians, professional engineers, and veterinarians. The consultants on social security report that "many if not all of these exclusions were made at the request of the groups excluded," but nevertheless recommend that they be included in the future.

One of the main reasons these groups have been opposing coverage under OASI is that they fear the long-term results of a trend toward Big Pensions and its sponsor, Big Government. When government begins to give rewards for long life to more and more persons, it begins an averaging process that eventually destroys individuality and initiative. Averaging is a traditional tool of socialists. Why save when the government will pay you if you live long enough and will pay your wife if you don't? A new meaning is coming to the words "social responsibility," which once meant that conscientious citizens would meet the needs of the unfortunate or indigent; the phrase soon will mean "individual irresponsibility," since the needs of all elderly persons will be met by a captive working force of younger taxpayers. The sense of one man's helping another will pass entirely if his major contribution to his fellow men is made through involuntary plans that theoretically insure him. A basic humanity requires that persons be responsible for one another—not that government tax Peter to pay Paul.

Obviously the medical profession can never approve of a federal, compulsory OASI system. Once Big Government produces compulsory pensions and theoretically similar minimum standards for all, it will attempt to bring standard health care to all. The pressure for compulsory health insurance follows in the wake of compulsory pensions. In this Congress more than 70 bills have been introduced to extend OASI and a large proportion of them deal with health benefits. Under all these schemes physicians would, in effect, become employees of the federal government by virtue of their absorption into the administration of the health benefits program.

Perhaps, among all the professional groups, physicians are the most allergic to federal domination because they have felt the hot breath of eager bureaucrats. Having failed to socialize us by frontal attack, they now seek to reach their objective by adding health benefits to the social security system on the one hand and federal subsidies to the voluntary health insurance system on the other.

CHANGES REQUIRED TO FORESTALL TOWNSENDISM

What, then, is the answer? Changes have been suggested by one of the authors (Dr. Dickinson) for the existing OASI system that would make it more sound, both economically and morally, as well as significantly lessening the danger of its mushrooming into an ever-larger welfare-state program. These proposed changes are not in accord with the present Chamber of Commerce policies. His suggested changes are:

"Three essential reforms of OASI are needed before any extension of it is justified. These are: 1. Jump the tax rate for employees over 50 years of age from 2% (after Jan. 1) to 6% of salary up to $3,600 a year. Jump the tax from 2 to 4% on those between 35 and 50 years of age and leave the rate unchanged at 2% for those under 35 years of age. The employer's tax rate would also be increased enough to preserve the 50-50 basis of contributions but should be the same regardless of the age of a particular employee. These sharp increases are necessary if employees, along with their employers, are to contribute the full costs of their OASI pensions for most of each age group before they retire. 2. Eliminate the work rule which prevents a person from drawing his social security pension between age 65 and age 75 if he earns more than $75 a month. In 1951 half of the self-employed physicians over 64 who retired did so after their 74th birthday. Under the present "work rule" they would be required to pay taxes but would receive no pension until reaching age 74, that is, those who live that long. 3. The extra income derived from these increased OASI taxes should be used to buy government bonds in the open market and these bonds should be canceled forever by the Treasury Department the day they are purchased. (Perhaps a small 'petty cash fund' might be advisable.) Over 5 billion dollars of the government debt could thus be retired annually. Similarly the 18 billion dollars of government bonds at present in the OASI trust fund should be canceled forever.

"If these three reforms were accomplished, a retired person could then accept his OASI pension starting promptly at age 65 with the knowledge that he was not robbing younger taxpayers, that he had prepaid a good share of the cost of his own pension. Most of his OASI taxes would have been used to retire the national debt. And the national debt is a real burden for the younger taxpayers.

"If the present administration would depart from the practice of the last two and call Old-Age and Survivors Insurance as now constituted, 'Old-Age and Survivors Charity,' the iniquities of the present system would be clear. Most workers are proud and do not need public charity; they would welcome the opportunity to prepay, with their employers, the full cost of their pensions. In all probability the people are far ahead of Washington in this matter of getting rid of the charity features of OASI by doubling or tripling the tax rate of the older workers."

It is especially urgent, however, to recognize that so long as this compulsory, federally administered pension system exists, the trend toward increased governmental responsibility and diminished personal responsibility cannot be completely reversed. Nor can any proposed changes in the existing system be critically examined without an awareness of the political nature of a federally administered pension plan whose board of directors is the Congress of the United States and whose beneficiaries are the older voters of the nation. The pressure for increased benefits is irresistible in such a system.

DYING OLD

This past half-century has brought striking changes in our way of life. Transportation improvements have made all points closer in distance; radio and television have made the nation closer in thought. New methods of warfare and defense have been frighteningly evident. Yet we have seen a more important development than these changes in material things; there has been an upward-sweeping surge in length of life. Dying old instead of dying young presents us with problems of attitude.

We need to reevaluate our approach toward old age. Much current thinking about the aged has dealt with the problem of supporting older persons financially. We tend to assume that we will always have an increasingly large nonproductive group over age 65 who will be dependent on social welfare. This shows an unwarranted lack of faith in what American medicine and American industry can do to develop the potentialities of older persons. Medicine's job is to keep them well enough to enjoy working. Industry's job is to find something useful for them to do. We have been encouraged lately to observe positive efforts to integrate older persons into our community and business life as productive units rather than merely to put them out to graze in ever greener pastures. Private enterprise has got to begin to think of methods of solving this problem in a private enterprise way. Older persons must be given the opportunity to be productive and thereby self-sustaining and self-respecting. We should not promote a planned old age of meager subsistence.

Those of us who are benefiting by health progress need now, more than ever, a moral philosophy to live by. We face life with the confidence produced by long life. We have faith that we will live to carry out most of our plans for our children and to see our hopes for them fulfilled. But is our longer lifetime giving us a clearer picture of our relationships, or are we closing our eyes to the next generation, thinking of our own desires, and losing our standards of right? Now as never before it is time to search for and cling to moral honesty. We can expect a long life. By what kind of social morality will we live?

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. Stormont, M.D., *Secretary.*

Hexamethonium Bromide.—Bistrium Bromide (Squibb).—$C_{12}H_{30}Br_2N_2$.—M. W. 362.21.—Hexamethylenebis(trimethylammonium bromide).—The structural formula of hexamethonium bromide may be represented as follows:

$$(CH_3)_3\overset{+}{N}-CH_2(CH_2)_4CH_2\overset{+}{N}(CH_3)_3 \quad 2Br^-$$

Actions and Uses.—Hexamethonium bromide is similar in its actions and uses to the salts of other quaternary ammonium compounds, such as tetraethylammonium chloride, which act as ganglionic blocking agents. Hexamethonium inhibits the transmission of nerve impulses through both the sympathetic and parasympathetic ganglia of the autonomic nervous system. Interference with the transmission of sympathetic stimuli causing vasospasm, particularly in the lower extremities, produces increased blood flow and hypotension. Simultaneous interference with the transmission of parasympathetic impulses produces loss of ocular accommodation, cessation or decrease of motility of the gastrointestinal tract, and alteration of bladder function.

Hexamethonium bromide is of limited clinical usefulness as a therapeutic and diagnostic agent in the management of peripheral vascular diseases. It may be beneficial in the treatment of thromboangiitis obliterans, arteriosclerosis obliterans, arterial embolism, diabetic gangrene, herpes zoster, acute thrombophlebitis, Raynaud's disease, acrocyanosis, trench foot, immersion foot, and various causalgias including reflex dystrophy. It may be employed diagnostically in acrovascular conditions to estimate the contribution of sympathetic stimuli in the production of vasospasm.

Hexamethonium bromide is also useful in the management of selected cases of hypertension. The drug is more effective for controlling episodes of severely elevated blood pressure than for mild hypertension. It may be helpful when used with caution in patients with severe hypertension and cardiac decompensation, but it is not likely to be effective in malignant hypertension with uremia. It should be used with caution, if at all, in patients with myocardial ischemia, cerebral ischemia, or encephalopathy and renal failure.

Since hexamethonium is more slowly and less completely absorbed by oral administration than by parenteral injection, the oral route is not recommended in the therapy or diagnosis of peripheral vascular disease. Because larger doses are required to produce the effects of the drug by the oral route, the use of the bromide salt in hypertension involves the regular occurrence of bromidism, so that *it should be administered only by parenteral injection.* Injections of the drug are not cumulative, but tolerance may develop in the management of severe hypertension. Upon injection, the drug produces its effects promptly and these usually persist from four to six hours. Following injection, the drug is excreted in the urine, whereas on oral administration a large portion passes through the intestinal tract in the stool.

Hexamethonium may produce peripheral circulatory collapse. Because of its hypotensive action, it should be employed with caution in all elderly patients and in those with arteriosclerosis. Its use is dangerous in patients who have recently lost blood because compensatory vasoconstrictor mechanisms are blocked. Side-effects occasionally observed include dilatation of the pupils, blurred vision, dryness of the mouth, postural faintness, transient nausea, vomiting, or drowsiness. Constipation may occur in some patients, which often can be managed by the concomitant administration of laxatives, repeated enemas, or temporary discontinuance of the drug. When the constipation is serious, paralytic ileus may result. This may be overcome by the oral administration of bethanechol chloride in doses of 5 to 10 mg. twice daily. Phenylephrine hydrochloride, 2 to 4 mg. intravenously, may be used to combat profound hypotension. Small doses should be used because hexamethonium increases the sensitivity to vasopressor agents.

Dosage.—Hexamethonium bromide is administered by parenteral injection intravenously, intramuscularly, or subcutaneously, depending on the rapidity of response desired. To induce ganglionic block, 90 to 135 mg. (50 to 75 mg. in terms of the ion) is given parenterally as a single dose. Heavier patients may require as much as 180 mg. (100 mg. as the ion), but the maximum dose should seldom exceed 90 mg. This produces a maximum response within a few minutes, which lasts for one hour and subsides gradually after four to six hours.

When repeated doses are necessary, the minimum effective dose is repeated every six hours, after meals and at midnight. Doses of 90 mg. or more may cause profound postural hypotension and occasionally a significant reduction in supine blood pressure. Patients receiving such doses for the first time should be kept in a recumbent position for three hours following the initial dose. Upon arising, each patient should be instructed to lie down at the first feeling of faintness. Subsequent doses usually do not cause such profound hypotension because of vascular adjustments. The initial dose may be given subcutaneously with the patient in a sitting position as an added precaution. For severely ill or debilitated patients, an initial dose of 1.8 to 9 mg. (1 to 5 mg. as the ion) should be used. This should be increased gradually, depending upon the response of the patient.

Tests and Standards.—

Physical Properties: Hexamethonium bromide is a white, tasteless, crystalline material with a faintly aromatic odor, m.p. 281-286°, when the sample is put in the bath at 265°. Hexamethonium bromide is freely soluble in methanol and water, soluble in alcohol, and insoluble in ether. The pH of a 1% solution is 6.2-7.0.

Identity Tests: Add 0.5 ml. of diluted nitric acid and 1 ml. of silver nitrate T.S. to 1 ml. of a 1% solution of hexamethonium bromide: a yellowish precipitate forms which is insoluble in nitric acid but slightly soluble in ammonia T.S. *(presence of bromide).*

Dissolve about 0.25 gm. of hexamethonium bromide in 5 ml. of water, and add 15 ml. of alcohol and 15 ml. of neutral sodium perchlorate [Add *cold* sodium hydroxide (100 gm./125 ml. of water) to a *cold* mixture of 300 gm. of 70% perchloric acid and 180 ml. of water, in an ice-bath, until the pH of the solution is about 7.0. Dilute the mixture to 500 ml. with water.]. Heat the solution on a steam bath to dissolve the precipitate initially formed. Cool the solution to about 10° and filter the mixture through a sintered glass filter of fine porosity. Wash the precipitate with cold alcohol and cold anhydrous ether, and dry at 105° for four hours: (*Caution! Care should be used in handling the dry material. It may be explosive.*) the hexamethonium diperchlorate obtained melts at 261-265°.

Purity Tests: Dissolve about 1.5 gm. of hexamethonium bromide, accurately weighed, in 200 ml. of water, add 5 ml. of saturated sodium bicarbonate, transfer quantitatively to a 250 ml. separatory funnel, and extract with 20 ml. of chloroform. Drain the chloroform layer into a 125 ml. separatory funnel and repeat the extraction of the aqueous solution with two 20 ml. portions of chloroform. Combine the extracts and wash them with 10 ml. of water. Filter the chloroform extract through a pledget of cotton into a tared 150 ml. beaker and wash the cotton with about 5 ml. of chloroform. Evaporate the chloroform on a steam bath and place the beaker in a vacuum desiccator for 1 hour: the amount of residue is not more than 0.5% *(presence of non-quaternary material).* Dry about 2 gm. of hexamethonium bromide, accurately weighed, in a vacuum desiccator over phosphorus pentoxide for 4 hours: the loss in weight is not greater than 1.0%.

Ignite about 2 gm. of hexamethonium bromide, accurately weighed, over a low flame, cool the residue, add 1 ml. of sulfuric acid, and complete the ignition: the amount of residue is not more than 1.0%.

Assay: (Bromine) Accurately weigh about 0.2 gm. of hexamethonium bromide and determine the bromine as described in the assay for bromide in the U.S.P. monograph for sodium bromide. Each milliliter of 0.1 *N* silver nitrate is equivalent to 0.007992 gm. of bromide and 0.01811 gm. of hexamethonium bromide. The amount of bromine present is not less than 43.0 nor more than 45.2%, equivalent to not less than 97.5 *nor more than 102.5% of hexamethonium bromide.*

(Hexamethonium Ion) Slowly and with constant stirring add 14.5 gm. of 70-72% perchloric acid to 960 ml. of glacial acetic acid contained in a 1,000 ml. volumetric flask set in an ice bath and mix well. Slowly add 24.2 gm. of acetic anhydride with constant stirring. Allow the solution to stand for 24 hours. Standardize the acid at 25° against potassium acid phthalate in glacial acetic acid (1:40), using 1% crystal violet in glacial acetic acid as an indicator and titrating to a blue-green end point. Transfer to a 250 ml. Erlenmeyer flask about 0.25 gm. of hexamethonium bromide, accurately weighed. Add 50 ml. of acetic acid, 10 ml. of a 2% solution of mercuric acetate in glacial acetic acid, and 2 drops of crystal violet indicator solution in glacial acetic acid and titrate with 0.1 *N* perchloric acid to a blue-green end point. Each milliliter of 0.1 *N* perchloric acid is equivalent to 0.01012 gm. of hexamethonium ion and 0.01811 gm. of hexamethonium bromide. The amount of hexamethonium ion is not less than 54.8 nor more than 57.0%, equivalent to not less than 97.5 nor more than 102.5% of hexamethonium bromide.

Dosage Forms of Hexamethonium Bromide

SOLUTION. *Identity Tests:* To an amount of solution equivalent to about 0.1 gm. of hexamethonium bromide, add 10 ml. of ammonium reineckate T.S.: a pink precipitate with a metallic sheen appears immediately.

To an amount of solution, equivalent to about 0.25 gm. of hexamethonium bromide, add 15 ml. of alcohol and proceed as directed in the identity tests for the active ingredient in the monograph for hexamethonium bromide.

Assay: (Hexamethonium Ion) Transfer to a 250 ml. Erlenmeyer flask an amount of solution, accurately measured, equivalent to about 0.125 gm. of hexamethonium ion. Add 50 ml. of acetic anhydride, attach an air-cooled condenser to the flask, and reflux for 10 min. Cool to room temperature, add 50 ml. of acetic acid, 10 ml. of a 2% solution of mercuric acetate in glacial acetic acid, and 2 drops of a 1% solution of crystal violet indicator solution in glacial acetic acid, and titrate to a blue-green end point with 0.1 *N* perchloric acid. Each milliliter of 0.1 *N* perchloric acid is equivalent to 0.01811 gm. of hexamethonium bromide. The amount of hexamethonium bromide is not less than 95.0 nor more than 105.0% of the labeled amount.

E. R. Squibb & Sons, Division of Mathieson Chemical Corporation, New York.

Solution Bistrium Bromide: 10 cc. vials. A solution containing 44.75 mg. of hexamethonium bromide in each cubic centimeter. Preserved with 0.9% benzyl alcohol.

Secobarbital Sodium (See New and Nonofficial Remedies 1953, p. 259).

Chemo Puro Manufacturing Corporation, Long Island City, N. Y.

Powder Secobarbital Sodium: Bulk; for manufacturing use.

Sodium Ascorbate (See New and Nonofficial Remedies 1953, p. 505).

The Vitarine Company, Inc., New York

Solution Sodium Ascorbate: 2 cc. ampuls. A solution containing sodium ascorbate equivalent to 50 mg. of ascorbic acid in each cubic centimeter. 5 and 10 cc. ampuls. A solution containing sodium ascorbate equivalent to 100 mg. of ascorbic acid in each cubic centimeter. All sizes preserved with 0.5% chlorobutanol.

Sodium Sulfacetamide (See New and Nonofficial Remedies 1953, p. 113).

Chemo Puro Manufacturing Corporation, Long Island City, N. Y.

Powder Sulfacetamide Sodium: Bulk; for manufacturing use.

REPORTS OF OFFICERS

(Continued from page 854)

REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association:

The Secretary respectfully submits the following annual report:

Membership

The year ending Aug. 31, 1953, again showed excellent progress in the Membership-Subscription Division of the Department of Records and Circulation. The upward trend in the membership income continued through 1952-1953 and resulted in revenue of $2,923,625.25 from paid members for the first eight months of 1953, as against $2,739,520.00 for the first eight months of 1952. The number of paid members increased by 7,323 for the first eight months of this year. The total was 117,063, while in the previous year it was only 109,740. A breakdown of the membership records as of Aug. 31, 1953, includes the following types and numbers of members.

Active paid members	117,063
Active members exempted from payment of dues	8,143
Associate members	3,886
Affiliate members	270
Honorary members	140
Service members	8,900
Total	138,402

The service member group includes full-time medical officers in the United States Army, Navy, and Air Force, and the Public Health Service, Veterans Administration, and Indian Service.

During 1953, 2,722 payments were received to cover 1952 dues, 924 payments to cover 1951 dues, and 334 payments to cover 1950 dues. These payments were obtained through letters sent directly to the member or through the state and county secretaries, who by their tireless efforts have helped bring these physicians back into the organization and put their names on the membership roster for 1953. Letters have been sent to some 6,000 members who have not yet paid 1953 membership dues calling attention to the fact that their names will be removed from the membership roster if payment is not sent within a reasonable time.

The following table shows the number of paid members in the states and territories for 1953 and 1952, as of Aug. 31, 1953.

	1953 Paid Members	1952 Paid Members
Alabama	1,264	1,203
Arizona	626	585
Arkansas	845	783
California	11,377	10,897
Colorado	1,331	1,346
Connecticut	1,988	2,014
Delaware	266	253
District of Columbia	1,034	942
Florida	1,903	1,749
Georgia	1,746	1,628
Idaho	432	415
Illinois	7,910	7,983
Indiana	2,824	2,759
Iowa	1,918	1,896
Kansas	1,206	1,054
Kentucky	1,447	1,416
Louisiana	1,398	1,278
Maine	492	431
Maryland	1,505	1,350
Massachusetts	4,099	3,603
Michigan	4,679	4,516
Minnesota	2,550	2,627
Mississippi	975	914
Missouri	2,505	2,438
Montana	407	385
Nebraska	1,095	1,105
Nevada	138	138
New Hampshire	393	434
New Jersey	4,478	3,923
New Mexico	369	349
New York	15,207	12,574
North Carolina	2,136	1,972
North Dakota	312	292
Ohio	6,090	5,553
Oklahoma	1,275	1,277
Oregon	1,235	1,099
Pennsylvania	9,718	9,614
Rhode Island	556	533
South Carolina	807	789
South Dakota	345	298
Tennessee	1,795	1,666
Texas	5,324	4,973
Utah	616	603
Vermont	339	326
Virginia	1,502	1,356
Washington	2,025	1,962
West Virginia	1,225	1,211
Wisconsin	2,689	2,628
Wyoming	205	188
Canal Zone	15	28
Hawaii	339	327
Puerto Rico	53	21
Alaska	55	36
Total	117,063	109,740

In 1953, for the first time, payments of membership dues were recorded on the I. B. M. system as the first phase of the conversion from the manual system. Plans are now being made to expand the use of the I. B. M. system during 1954 to expedite sending out membership cards at the time dues are recorded. In addition, the records of exempt, associate, and service members are being converted to the I. B. M. system to facilitate sending membership cards and to speed up the tabulation of data. Many problems still confront the Association if membership records are to be accurate and up-to-date. The long delay between the time the physician pays his American Medical Association dues and the time the dues are received at Association headquarters is a major problem. One of the main difficulties is in notifying a physician that his membership dues are payable. In many states the physician is billed in January for his state dues and two or three months later for his American Medical Association dues. Where the secretary sends a bill for the county, state, and American Medical Association dues at one time, it generally speeds up the payment of dues. The delay in receiving the payments is especially serious when it concerns a new member of the American Medical Association, as such names can not be placed on the mailing list to receive THE JOURNAL or one of the specialty journals until payment is received by the American Medical Association.

Many members have been reported this year as new members with a payment of $25.00 for 1953 dues. A check of the records reveals that these physicians had been members of a constituent association in 1950 and therefore must pay $25.00 delinquent dues for that year. County and state secretaries have not realized that in taking a new member into the American Medical Association it is necessary to collect these old dues. It is only after several letters that it is possible to collect the back dues, and, in a number of cases, such members will have to be dropped at the end of this year if they do not comply with the Bylaws. The number of members who have been delinquent in the payment of dues for 1951, 1952, and the present 1953 has been greatly reduced. Many of the names that appear on our 1953 unpaid list turn out to be physicians who are in the Service, in residencies, or have left the state and joined elsewhere but the state secretaries have failed to notify this office.

Another problem is the variety of membership classifications in constituent associations, which causes confusion as to the type of membership a physician may hold in the American Medical Association and, consequently, the number of members that may be counted for representation in the House of Delegates. Because the problem arises out of provisions in the constitutions and bylaws of the constituent associations, it can not be easily or quickly solved. In many states active membership is given only to physicians in practice. Also in many states when a member of the constituent association retires, suffers physical disability, or enters on active duty in the Army, Navy, or Air Force, his type of membership changes to a category that does not give him the right to vote and hold office in the constituent association. Such physicians may then be given associate membership in the American Medical Association and can not be counted in its total of active members. In some states, an emeritus or honorary membership is given to some physicians at the age of 65 or possibly after 40 years of practice, excusing them from payment of local and state dues. Such physicians are frequently disappointed to find that they must continue to pay dues in the American Medical Association until the January first following their 70th birthday. Other states give a junior membership to physicians during the first few years of practice as well as to interns and resident physicians, but such members are eligible to exemption from payment of American Medical Association dues only if they are taking postgraduate training within five years of graduation.

Other sources of misunderstanding are the uses of the terms, associate, affiliate, honorary, service, and veteran, to designate categories of membership. Physicians holding one of these types of membership in a constituent association assume that they hold a like-named membership in the American Medical Association. If they are exempted from payment of dues in their county and state societies, they then think they should be exempted from payment of dues in the American Medical Association. One of the most misunderstood situations is the fact that when a physician is exempted from payment of dues he feels he has been exempted from payment for The Journal of the A. M. A. or any publication he may be receiving through the benefit of membership. Specific recommendations have been made in conferences with officers of one or two state associations, and as a result changes are now being made in the constitutions and bylaws of those organizations to provide active membership for physicians who are eligible for exemption from payment of dues. Other states have already made changes and in some cases have added new categories of membership. A new survey is being made of the constitutions and bylaws of constituent associations with respect to provision for exemption from payment of American Medical Association dues. Further recommendations can be made at the completion of the study.

Subscription and Circulation

The number of subscribers on the mailing list for The Journal was about the same as in 1952, although many members substituted one of the special publications in place of The Journal. All of the nine special publications showed an increase in circulation.

It has been possible during the period of collecting dues from delinquent members to maintain the circulation of The Journal at its present level. Every effort was made to collect back membership dues rather than to take the name off of the membership subscription list without giving the member or subscriber every opportunity to pay. In the majority of instances, the subscriber finally paid up after he understood the situation.

All of the nine specialty journals showed an increase in circulation. While part of this gain is accounted for by the fact that physicians substituted one of the special publications for The Journal, on their membership, there was a number of new orders from specialists and, most of all, a very high renewal average.

Field Activity

There have been numerous calls on the Secretary and the Assistant Secretary, as in previous years, to attend and participate in meetings of state medical associations and county medical societies. Such invitations are greatly appreciated and are accepted whenever possible, even though attendance at so many entails considerable time lost from work at headquarters. An efficient and willing staff, not only in the Secretary's Office but also throughout the various departments, keeps essential routine work well in hand. The Secretary and/or Assistant Secretary have also attended and taken part in meetings of other organizations with which the American Medical Association maintains cordial relations and have served on committees or in an advisory capacity. They have also appeared before hearings of congressional committees to present the views of the Association with respect to proposed legislation of interest to medicine. In addition, an earnest attempt is made to attend at least a portion of all meetings of the Association's own committees and Councils.

Directives of the House of Delegates

The Secretary has made disposition of resolutions and recommendations adopted by the House of Delegates at the New York Meeting which were not specifically directed to the Board of Trustees or stated Councils or committees.

Resolution on American Medical Education Foundation.—The attention of the executive officer of each constituent association was drawn by letter to this resolution, which recommended that all state medical associations follow the plan of the Illinois State Medical Society whereby a stated sum of money is collected from each member and earmarked for the Foundation. One reply has been received in the form of a resolution which may be introduced at the St. Louis Meeting.

Resolution on Payment of Back Dues.—This resolution requested the Association to alter its regulations so that payment of membership dues for a current year "without the payment of any back dues" would be sufficient for membership in good standing of those members of constituent associations who have not heretofore paid American Medical Association membership dues. The Reference Committee on Amendments to the Constitution and Bylaws recommended that the resolution and its report be studied by the state medical associations, and that the resolution be considered again at the December, 1953, meeting. This was pointed out in a letter to each state association executive officer. One reply has been received, also in the form of a resolution which may be presented to the House.

Resolution on Expression of Appreciation to Physicians of Korea.—This resolution was forwarded to the Korean Ambassador at Washington, D. C., Dr. You Chan Yang, who replied as follows:

> I have your letter of September 2, 1953, with a copy of the resolution of appreciation adopted by the House of Delegates of the American Medical Association at its annual session held in New York City in June and expressing the appreciation of the American Medical Association for the physicians of Korea because of their valiant work during the communists' attack on the Republic of Korea.
>
> Being a physician myself, I am very proud of my American colleagues for the beautiful sentiments embodied in the resolution, and I wish to take this opportunity to express my personal gratitude to the members of the American Medical Association.
>
> I am sending your resolution to the Korean Medical Association in Korea, and I am sure you will hear from them in the very near future.

Resolution on Executive Order of President of the United States.—This resolution, which recommended the rescinding of Section 8 (a) (1) (iv) of Executive Order 10450 dealing with security requirements for government employees, was transmitted to the Special Assistant to the Secretary of Health, Education, and Welfare, Dr. Chester S. Keefer, who replied that "the matter . . . has been referred to the Department of Justice for consideration and advice," and that "when definitive information has been developed it will be "forwarded" to the American Medical Association. No further communication has yet been received.

Resolutions to be Introduced at St. Louis Meeting

At the time of preparation of this report, four resolutions to be presented at the St. Louis meeting of the House of Delegates have been received by the Secretary. The resolutions deal with chiropractic and naturopathic education, principles of medical ethics, ethical advertising, and medical school training and will be introduced by the delegations from Alabama, Iowa, West Virginia, and Utah, respectively.

The Collier's Article

The Secretary would like to call to the attention of the House of Delegates an incident concerning *Collier's* magazine, which, in its issue of Oct. 30, 1953, published an article entitled "Why Some Doctors Should be in Jail." The writer, Howard

Whitman, during his preparation of the article asked the Secretary for an official statement regarding American Medical Association policy with respect to fee splitting, and the statement was given to him. Unfortunately, when the article was published the statement plus a photograph appeared in close juxtaposition to the title, leaving the false impression in the minds of many physicians that the Secretary had reviewed the title and the article and approved them before publication. The Secretary wishes the record to show clearly that he never saw the article, the title, the illustrations, or the cover page of that issue of *Collier's* before publication. Had it been submitted to him he would have strongly protested.

In Appreciation

The Secretary again offers an expression of his sincere gratitude and appreciation for the many courtesies and the kindly assistance extended to him by the members of the House of Delegates and by the officers and members of official bodies of the Association and of the constituent and component societies. The headquarters personnel, which now totals 823 full-time workers in the office and mechanical departments, deserve a word of praise and appreciation for their continued loyal and helpful contributions to the administration of the Association's affairs.

Respectfully submitted,

GEORGE F. LULL, Secretary.

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

The following annual report of the Board of Trustees is respectfully submitted.

(Concluded from page 854)

The Journal of the American Medical Association

THE JOURNAL is still maintaining a publication schedule which permits the issuance of larger and more complete numbers. While most of the articles are primarily of interest to general practitioners, many other statements of particular interest to specialists are included. There is a limit to the number of papers that can be published, but the desires and needs, suggestions, and criticisms of the readers are kept uppermost in mind as communications are selected for publication. In 1950 a thorough study was made concerning the editorial content of THE JOURNAL. Following this study many changes were made, and others will follow as expediency permits. In 1953 another study was made to encompass editorial and advertising problems, and this study also will serve as a guide for future plans.

The circulation, domestic and foreign, of THE JOURNAL is steadily increasing, which, while encouraging, at the same time increases production difficulties. Perhaps it is not well known that there are printed each week approximately 167,000 copies even though the cover carries the statement "This issue exceeds 150,000 copies."

While not all departments have equally large numbers of readers, interest in most departments seems to be growing yearly. Perhaps the best evidence of this lies in the correspondence received, the number of times passages are quoted and repeated elsewhere, and, of course, the prompt response when an error occurs. A new department introduced in the last several months is "The Leisure Corner," which is directed toward the hobbies of physicians.

Some of the departments of the Association provide much material for THE JOURNAL during a year. In fact, several issues are dedicated to special subjects. However, there is a limit to the size of a single issue because of mechanical production difficulties, mailing, and costs, and it may be necessary to consider condensation of some of the special issues. Such action cannot be taken lightly, as THE JOURNAL plays an important role in the dissemination of such information. Another indication of the role of THE JOURNAL in the activities of the Association can be gained from the financial reports offered by the Board of Trustees, which reveal the status of is periodical as a source of income.

The Current Medical Literature section contributes to THE JOURNAL weekly 12 to 16 pages of abstracts culled from universal medical literature. The material for abstracts is furnished by some 1,200 publications subscribed to or received by the Library of the American Medical Association. An attempt is made to report on the most important clinical work, research, and biological problems related to medicine and which are primarily of interest to the practitioner. The department also furnishes abstracts for the *A. M. A. Archives of Industrial Hygiene and Occupational Medicine.* It translates foreign letters sent to THE JOURNAL by its correspondents in the various countries, business letters, and all foreign correspondence received by the Association.

During the first eight months of 1953, the Medical News department of THE JOURNAL continued to show an increase in the number of items published. A survey of the periods covered by the past three reports shows that in the first months of 1951, 1,457 news items were published; in the analogous period of 1952, 1,699, and in 1953, 1,960. A breakdown, prepared to determine state coverage, reveals that a few states have been consistently and regrettably unproductive of news. Obviously, either nothing of importance ever happens in these states or they are too modest or indifferent to report their activities through the available channels of communication. Special efforts will be made through the coming year to encourage and increase the news items from these states. The number of obituaries published has also steadily increased, as have the clippings disseminated to various individuals and departments in the organization, and the requests by telephone and letter for information on a great variety of subjects. The increased use of photographs of hospitals, medical headquarters, university projects, etc., has added to the interest and effectiveness of the pages.

The Queries and Minor Notes department of THE JOURNAL received more inquiries than in any previous year. The number of letters received during the first nine and one-half months of 1953 is approximately 1,800, which if projected over a 12 month period should be more than 2,400. This compares with 1,100 inquiries in 1949, 2,100 in 1951, and 2,200 in 1952. Another indication of the growing interest in this section of THE JOURNAL is the number of letters commenting on the Queries and Minor Notes published. While not all of these appear in THE JOURNAL, many are published. For example, in 1951 approximately 70 appeared in THE JOURNAL pages, in 1952 there were 80 published, and in the first eight months of 1953 there were 70. Volume III of "*Selected Questions and Answers*" is out of print already. Six thousand copies were sold and many orders were received that could not be filled. While there have been numerous requests for volume IV, plans for issuing this volume have not yet been made.

Specialty Journals

On Aug. 1 Mr. Gilbert S. Cooper became Managing Editor of the Specialty Journals. He formerly was Director of Sales for the Blakiston Book Company. He has had broad experience in the selection and training of personnel, the development of production programs, and editing and sales. His special training and knowledge will be directed toward making the Specialty Journals even more helpful to more physicians as economically as possible but within the boundaries of good publishing.

The Specialty Journals department is now undergoing intensive study and analysis with the intention of making it a commercial operation with respect to manpower requirements, method improvement, and production and cost controls. This does not imply that the department is motivated by the desire for profit. It does mean that it seeks to operate within such limits as to provide for production and overhead costs, with consideration for depreciation of equipment which will need repair and possible replacement.

METHODS IMPROVEMENT

A review of operating procedures is a continuing function of good management. Supervisory personnel of the Specialty Journals will be prepared to observe procedures under the Managing Editor's control with such critical attitude that details without purpose and, therefore, unnecessary, will be eliminated. He will look at other details with intent to combine them to reduce handling, and rearrange for better sequence. Wherever possible, he will be expected to simplify details so that they are more easily performed.

There is a very close relationship between office production and methods improvement. A close study of Specialty Journal activity, from receipt of manuscript to the release of a journal issue, will result in a realistic publication schedule. Necessary adjustments both in schedule and in sequence of operations will work toward a superior control. The importance of this phase of publishing cannot be overemphasized. A guaranteed release date for each issue has a desirable effect upon the subscriber and advertiser, and has a tendency to attract both. Constant attention to this matter is essential and will be encouraged.

Cost Control

This department is interested in breaking down production costs on the basis of the following factors for each issue: (1) text section: composition, author alterations, engravings, printing—text, paper—text, cover—presswork and binding, cover—stock, printing of special inserts, stock for special inserts, inserting, and (2) ad section: composition, printing black form, printing color form, paper for ad section, and number of inserts and cost.

During the first nine months of 1953, the Specialty Journals have published 605 original articles, 30 progress reports or general reviews, 145 case reports or clinical notes, and 19 editorials. Accepted articles waiting publication: surgery 43, pathology 25, otolaryngology 52, ophthalmology 29, neurology and psychiatry 21, internal medicine 42, industrial hygiene 33, dermatology and syphilology 73, and diseases of children 42. The total of all unpublished articles for all Specialty Journals is 400. It is anticipated that 266 more papers covering articles, progress reports, general reviews, case reports, clinical notes, and editorials will be published during the remainder of 1953.

Circulation figures for all nine Specialty Journals show an increase, as of Aug. 31, 1953, over 1952. *Archives of Surgery* has increased 440; *Archives of Otolaryngology* 90; *Archives of Dermatology and Syphilology* 282; *Archives of Industrial Hygiene and Occupational Medicine* 95; *Archives of Pathology* 136; *Archives of Internal Medicine* 374; *Archives of Ophthalmology* 245; *Archives of Neurology and Psychiatry* 203; *American Journal of Diseases of Children* 262. For all Specialty Journals the total increase has been 2,127.

Standard Nomenclature of Diseases and Operations

The Editorial Advisory Board for the fifth edition of "Standard Nomenclature of Diseases and Operations" met on March 7, 1953, and 23 working committees were appointed. These committees are composed of leaders in their respective fields, who will work in close collaboration with the editors in making consistency changes, deletions, and additions. Scientific knowledge gained in the interim between publications requires many changes in the scientific material presented. The working committees approve or disapprove of these latter changes.

In November, 1952, and March, 1953, standard nomenclature was taught at five-day institutes for medical record librarians, sponsored jointly by the American Hospital Association and the American Association of Medical Record Librarians. The nomenclature institute teaching was under the direction of the associate editor, Mrs. Adaline C. Hayden. Standard nomenclature classes were also taught by Mrs. Hayden at meetings and local institutes in New York, Indiana, Iowa, and Massachusetts. Through these mediums approximately 1,000 record librarians have received instructions in the use of nomenclature. A special course in standard nomenclature sponsored by the Committee on Education of the Chicago Medical Record Librarian's Association was conducted at weekly intervals covering a period of nine weeks during April, May, and June, 1953.

The nomenclature is now being used by 74.5% of the hospitals in this country and has a considerable foreign distribution. Approximately 2,300 nomenclature queries have cleared through the Association's headquarters office during the past year.

Quarterly Cumulative Index Medicus

Volume 50 (July to December, 1951) of the Quarterly Cumulative Index Medicus was published in June, and it is anticipated that volume 51 (January to June, 1952) will be available by the end of the year, since the editorial work was completed in August. Cards for volume 52 (July to December, 1952) were all assembled in September, and editing of the copy for reproduction of this issue is well under way.

In the meantime progress has been made in the preparation of a third edition of the Quarterly Cumulative Index Medicus Subject Headings, which is long overdue, the second edition being outdated and no longer satisfactory for use by the editorial staff. Because this new edition will entail a number of changes, the production of the long-awaited volume 45 (January to June, 1949) will be undertaken after volume 52 is processed and before the revision of subject headings is adopted. It has been necessary to cut the number of periodicals included in this volume and limit its coverage to those which are deemed most valuable to users. Although considerable objection to this procedure and differences of opinion regarding the journals selected are anticipated, the decision to curtail this issue was made only after careful consideration.

A reduction in coverage will be noted in volume 50, which includes about 1,000 periodicals on the list of those indexed. However, this means very little change in the number of articles entered, since almost every periodical has increased in size during the past few years. At the same time, 21 journals were added in this volume. Many of those removed are available in only a few libraries in this country, and others appear so irregularly that they are not dependable. Most of them will be reconsidered as soon as improved conditions warrant an increase in the number of publications handled.

In evaluating a periodical for inclusion in the index, the following questions are asked: Is the periodical well edited? Is it widely read? Is it the official publication of an organization of some standing? Does it contain original articles? Are they well developed presentations? Do they make a contribution to medical knowledge or practice? Are they of more than local interest? In addition, there are other criteria for publications in related fields or in foreign languages, for hospital bulletins, for specialty journals, and others which fall into separate categories.

Beginning with volume 51, a new feature has been added to the bibliographic information furnished by the index: symbols indicating foreign languages appear at the end of the subject entries and of any author entries with titles translated into English. This will aid the user in determining immediately what language is involved in case this point is not apparent from the abbreviation for the periodical cited.

Library

In accordance with the plan to build up the book collection of the library, especially in certain fields, about 800 items were added this year. These are almost entirely recent publications acquired by gift or purchase, which bring the total collection to approximately 4,065 volumes, including bound serials.

A physical rearrangement of one of the most valuable files in the library, the cumulation of entries in the indexes of The Journal, has been accomplished. For convenience, the file of authors is in three parts, the first including cards for the years 1911-1932, the second extending through 1944, and the third beginning with the next year. A separate subject file begins with 1911 and extends through 1950, a new file having been started in 1951 in order to make the entries for recent volumes more accessible. The author and subject cards covering book reviews published in The Journal are contained in a special file. The index cards for the 1953 volumes were added to these collections as they were prepared in the library.

Requests for periodical loans and package libraries have fallen behind the demands of previous years, probably in a large part due to the availability of similar services to physicians locally. These facilities have fortunately improved in the last years even for borrowers in rural areas. Although the package library service was originally intended for physicians in such locations, a check of loans for this year shows that 45% were made to borrowers in cities with over 50,000 population. The records are naturally influenced by the location of the Association in Chicago, since 98 packages were loaned in the city and its suburbs in the first nine months of the year. Twenty went to New York City, 8 to Brooklyn, 10 to Philadelphia, 8 to Los Angeles, 7 to Boston and 11 to Memphis, the home of a regular borrower who writes, "If the whole medical profession knew about your library, they would all be better doctors." It is gratifying that every state is represented, however.

The periodical loans present a different geographical picture because many librarians, knowing the generous resources of the library's periodical collection, borrow for individuals whom they serve and because certain physicians make continuous use of this privilege. The Chicago area accounts for over 15% of the loans, but here again the service reaches every state.

The number of subject headings covered by package library loans has increased 15% over last year's figure of 420. Sixty-seven requests were for material on cancer and other tumors, 66 on ophthalmology, 28 on toxicity of specific drugs, 22 on anesthesiology, 18 on alcoholism, and 12 on tobacco. Tuberculosis, poliomyelitis, diabetes, multiple sclerosis, and peptic ulcer were the specific diseases that brought the most inquiries.

In addition to requests for periodical loans and package libraries, the library answered about 700 letters involving reference work. Mention should also be made of the numerous telephone calls and personal inquiries from visitors and the headquarters staff.

Report of Department of Records and Circulation

DIRECTORY-BIOGRAPHICAL DIVISION

Work on the 19th edition of the American Medical Directory was deferred again during 1953 so that current information on the membership status of physicians could be transferred to the biographical records. In 1950, the membership structure of the American Medical Association was changed, so that a physician who was a member of his constituent association was no longer automatically a member of the American Medical Association. This structural change, the confusion resulting from the collection of membership dues through the county and state societies, the new types of membership in the Association based on the physician's membership classification in his constituent association, and the work of transferring the membership records to an I. B. M. system, have been the principal factors which have delayed the establishment of accurate and current records. In the next edition of the Directory, the following types of membership in the American Medical Association will be indicated: (1) active membership; (2) associate membership; (3) affiliate membership; (4) service membership; and (5) honorary membership.

As of Sept. 1, 1953, biographical information on 31,993 new physicians has been added to the Directory records, and 151,503 changes of address have been recorded. Of this number, 57,978 were local changes, 92,032 were changes from one city to another, and 1,403 were miscellaneous changes. Because of death, the names of 14,625 physicians were deleted. Before the end of 1953, information cards will have been sent to all physicians listed in the biographical records, requesting up-to-date information on residence and office addresses, and type of practice. According to current plans, the 19th edition of the Directory should be completed and ready for delivery late in 1954.

The sale on the 18th edition of the American Medical Directory, issued in June, 1950, was 19,540 copies, which exhausted the supply of this issue. The final sale on the 1950 edition compares with a sale of 7,899 copies of the 17th edition, published in 1942, and a sale of 7,322 copies of the 16th edition, published in 1940. The income from the sale of the book, from advertising receipts, and particularly from the Directory Report Service (a supplementary service furnished on a subscription and service-fee basis to large mailers of circular material) has helped to defray the expense of maintaining the records of the Directory Division.

The Directory-Biographical Division continues to act as a clearing house of information on physicians for most of the Councils, Bureaus, and Departments of the Association, as well as for other official bodies, commercial and philanthropic organizations, government agencies, and the lay public. During the past year, the information section of the Directory Division has handled an average of 100 telephone calls a day and more than 5,200 mail inquiries during the year concerning physicians. In addition, more than 9,000 membership applications have been checked for the Secretary's Office; 5,000 license applications have been processed for the Council on Medical Education and Hospitals; and 2,200 applications have been checked for five of the examining boards in a medical specialty. The division routinely checks information on authors, participants in meetings and conferences, prospective advertisers, and correspondents for various Headquarters' activities. The Directory-Biographical Division, as a part of the Department of Records and Circulation, has worked closely during the past two years with the Membership-Subscription Division in clarifying the location, professional appointments, and membership status of physicians.

MEMBERSHIP AND SUBSCRIPTION DIVISION

The report on the work of the Membership and Subscription Division will be found in the Report of the Secretary.

Report of Committee on Mental Health

This is the first annual report of the Committee on Mental Health since its appointment by the Board of Trustees in late 1951. Present members of the Committee are Drs. Leo. H. Bartemeier, Chairman, Detroit; Lauren H. Smith, Vice Chairman, Philadelphia; Walter H. Baer, Peoria, Ill.; Hugh T. Carmichael, Chicago; Francis M. Forster, Washington, D. C.; M. Ralph Kaufman, New York; Maurice Levine, Cincinnati, and Richard J. Plunkett, Secretary, Chicago.

The establishment of this Committee as a standing committee of the Board of Trustees relates historically to the formation of a temporary Committee on Mental Health, which was appointed by the Board in 1930 and of which the late Dr. H. Douglas Singer, Chicago, was Chairman. The temporary committee was carried through July, 1933, during which time an over-all study of mental health practices in the United States was made and a report published in the Proceedings of the House of Delegates, 84th Annual Session, Milwaukee, Wis., June, 1933. This report covered the general aspects of mental health work at that time, such as scope of treatment, preventive practices in mental illness, relationship between the medical profession and lay groups in mental health, organization for mental health education, and legal aspects of mental illness. The temporary committee recommended that a permanent bureau or committee on mental health be established "to take such steps as will enable the profession as a whole to assume the leadership in mental health which is its proper responsibility." A permanent committee was not formed at that time, however. The tremendous extent of the problem became apparent in the interim and, with the growing recognition of the need for closer liaison between psychiatry and general medicine brought more sharply to attention by experience gained in World War II, it became evident that a standing committee devoting its efforts only to this field was necessary.

The first official meeting of the Committee on Mental Health was held at Association headquarters in March, 1952. At this first meeting officers were elected and an executive committee appointed. The Committee gave consideration at its first meeting to the many problems which the members felt would be of sufficient interest to warrant further study. These included:

1. Medical education
   (a) Undergraduate
   (b) Postgraduate
   (c) Special work for persons not in the field of psychiatry
   (d) Relationship of residency training to certifying boards
2. Psychology
   (a) Training of psychologists (how much psychiatric training is being given and under what supervision)
   (b) Licensure (certification, which should specify definition and duties)
3. Psychiatric units in general hospitals
4. Stimulation of medical students and other personnel (medical) to train in the field of psychiatry
5. Improvement of state mental hospitals and private psychiatric hospitals
6. Laws relating to commitment to hospitals for mentally ill

7. Laws relating to special groups (such as sex offenders, those under indictment for crime, etc.)

8. Development of outpatient clinics (mental health clinics)

9. Research in mental illness.

The next regular meeting was held on July 10 and 11, 1952, at which time Dr. Richard J. Plunkett was appointed as full-time secretary with offices to be set up at Association headquarters on Sept. 1, 1952. Dr. Daniel Blain was appointed as consultant to the Committee. The Committee has now held seven meetings, three in 1952 and four in 1953.

Licensure or Certification of Clinical Psychologists

One of the first matters of importance referred to the Committee concerned the official attitude of the Association toward licensure or certification of clinical psychologists. The Committee reviewed a report on this subject which had been prepared by Drs. Gerty and McKay and Mr. Holloway of the Bureau of Legal Medicine and Legislation, and consulted with members of other interested groups. The Committee recognized the complexity of the problem and with few exceptions agreed with the manner in which the problem was presented in the body of the "Gerty Report." However, inasmuch as the Committee felt that clinical psychologists could not in any way be qualified by their training and experience to function independently as psychotherapists, it recommended that the Association adhere to a policy which defines the practice of psychotherapy as an integral part of the practice of medicine and that the Association present a medical point of view in relationship to any attempt to recognize the clinical psychologist legally.

Psychiatric Communications Privileged

Because of its importance to psychiatrists particularly, the Committee gave consideration to a request for support in a situation where a psychiatrist was asked in court to give information relating to personal matters that may have been disclosed to him by a private patient. The psychiatrist had refused to testify before a notary with the conviction that the communications between the patient and the psychiatrist were or should be privileged. The opinion rendered in this matter by Judge Harry M. Fisher in the Circuit Court of Cook County, Ill., was believed by the Committee members to be of such importance to psychiatrists and physicians with reference to the patient-doctor relationship that arrangements were made for its publication. This report appeared in the Nov. 22, 1952, issue of The Journal.

Mental Health Activities of State Medical Associations

Following a letter survey addressed to state medical associations concerning the activities of these associations in mental health, the Committee compiled a report for distribution to the state associations and included a list of 13 suggested activities in which state association committees on mental health might take an active interest. They are as follows:

1. Study of Blue Cross-Blue Shield and other medical service plans to determine ways by which these plans may more effectively provide for treatment of mental and emotional illness.

2. Establishment of citizen groups for promotion of mental health education services (women's auxiliaries).

3. Recommendations to legislatures for increased budgets for mental institutions. (The present average is about $2 per patient per day for patient maintenance.) It has been demonstrated that this low budgetary level is responsible in great part for the present nationwide difficulty in properly caring for patients in mental institutions. The Committee on Mental Health of the American Medical Association and the American Psychiatric Association are both in agreement that budgetary levels need to be materially increased. Under present conditions, they should approximate a level of $5 per patient per day.

4. Serving as a central office for dissemination of information on programs for mental health to the medical profession and public.

5. Efforts toward the establishment of psychiatric departments or services in general hospitals and increasing other psychiatric services in the community.

6. Recommendations to legislative committees of state medical associations that changes or amendments be made in medical practice acts to include mental illness and psychotherapy as being within the legal definition and responsibility of the practice of medicine.

7. Improvement of facilities and level of professional care in state institutions for care of the mentally ill.

8. Establishment of facilities for psychiatric consultation to courts and penal institutions.

9. Review and sponsorship of legislation for state mental health activities relating to problems of alcoholism and addiction.

10. Sponsorship of improved state laws for commitment to mental institutions and provision for and encouragement of voluntary admissions to mental institutions.

11. Sponsorship of programs for postgraduate education of physicians in the utilization of psychiatric principles in the practice of medicine.

12. Sponsorship of programs in psychiatry and mental health in county medical society meetings during Mental Health Week in May of each year.

13. Encourage the setting up of collaborating committees on mental health in all county medical societies.

National Conference on Mental Health

The Committee has planned, with the responsible officials of the American Psychiatric Association, for a conference to be jointly sponsored by the American Medical Association and the American Psychiatric Association with representatives of some 60 or more national organizations that are actively interested and working in the field of mental health. This meeting will be held on Oct. 24 and 25, 1953, in Washington, D. C. The purpose of the conference will be to provide for an interchange of information about organizational activities and to promote more effective collaboration among the participating organizations. The conference will cover the general topics of education in mental health, research in mental health, treatment in mental illness, and prevention of mental illness. A report of the proceedings will be published following the meeting.

Subcommittee on Alcoholism

In October, 1952, the Committee on Chronic Diseases disbanded its subcommittee on alcoholism, and the problem was transferred to the Committee on Mental Health. In June, 1953, the Committee met with Drs. Harold W. Lovell, Selden D. Bacon, and Marvin A. Block to discuss the setting up of a new subcommittee under the Committee on Mental Health. The question of what direction the new subcommittee on alcoholism should take in relation to medicine as a whole was discussed in considerable detail and the objectives tentatively outlined as follows:

1. To promote the inclusion of proper teaching on alcoholism and its treatment in the curriculum of medical schools throughout the country;

2. To promote the establishment of committees on alcoholism in both county and state medical societies;

3. To establish terminology and definition in the field of alcoholism;

4. To urge medical service insurance companies, the Blue Cross-Blue Shield, etc. to accept and treat alcoholism as a disease, giving full coverage under present policies as is now done for other diseases, and

5. Passage of new legislation to get rid of present antiquated laws.

Following this meeting it was decided that the appointment of the new subcommittee should be temporarily deferred until the Committee has had opportunity to make several field studies of programs in alcoholism that are operating effectively within or under the sponsorship of state or county medical societies.

Headquarters

Through its headquarters office the Committee has been working out means for effective collaboration with other committees and bureaus in the aspects of their work that pertain to psychiatry and mental health. Useful mutual contacts have been established with the Woman's Auxiliary, Bureau of Legal Medicine and Legislation, Bureau of Health Education, Council on Medical Education and Hospitals, Council on Physical Medicine and Rehabilitation, Committee on Medical Motion Pictures, Council on Industrial Health, Bureau of Investigation, and Department of Public Relations.

Future Plans

At the present time the Committee is undertaking exploratory discussions with the chairman and members of the Central Inspection Board of the American Psychiatric Association toward the formation of plans for a cooperative effort between the Committee on Mental Health and the Central Inspection Board for the inspection and rating of United States and Canadian mental institutions. The Committee feels that such a cooperative effort would bring the combined effect of the prestige of both the American Medical Association and the American Psychiatric Association toward raising the standards of care and treatment of patients in mental institutions, which are now in most instances considerably below the standards of general hospitals. Certain tentative proposals have already been made, but these have not as yet been approved by the members of the Central Inspection Board.

Report of Council on Pharmacy and Chemistry

The Council on Pharmacy and Chemistry has continued to serve the medical profession primarily through its program of critical evaluation of new drugs in order to ascertain the true value, hazards, and limitations of these agents. There is no doubt that the present era in medicine is characterized by revolutionary developments in the field of therapeutics. New drugs are being introduced at an increasingly rapid rate. Many of these new medicinal agents are extremely potent and capable of doing more harm than good if administered without due appreciation of their contraindications or observance of necessary precautionary measures. The average physician has neither the time nor the facilities to experiment with new drugs in order to determine proper indications for use, dosage, undesirable side-effects or hazards, and the precautions necessary to allow for relatively safe use. He must rely on reputable sources for complete information in this regard. The efforts of the Council to provide authoritative information on the proper usage of medicinal agents are being appreciated to an ever-increasing extent.

Evaluation of Drugs for Acceptance

The drug acceptance program continues to be the major activity of the Council. The success of this program is largely dependent on those pharmaceutical manufacturers who voluntarily cooperate with the Council by submitting worth-while new products for evaluation. The continued expansion of the program offers proof of increasing cooperation by the drug industry. During the period from Sept. 1, 1952, to Sept. 1, 1953, there were 282 drug products submitted for acceptance. This represented an increase of 82 over the previous year. Of all the drugs submitted this past year 37 represented distinctly new contributions to the medical armamentarium. This represented an increase of eight over the previous year. It would thus seem apparent that pharmaceutical firms in general are fairly well satisfied with the Council's rules governing acceptance and are not fearful of having worth-while products subjected to scrutiny and evaluation by an independent body of experts in the field of therapeutics.

Selection of suitable trade and nonprotected names for new drugs is becoming increasingly difficult. Not infrequently drug firms approach the Council regarding the acceptability of proposed nomenclature for new drugs before such products are ready for the market. By collaborating in this manner needless embarrassment or delay in acceptance has often been obviated.

The Council has come to depend to an increasing extent on consultants in various specialties for advice or assistance in resolving many questions relating to the propriety of new claims for medicinal agents. The valuable services of these consultants has often made it possible for the Council to keep pace with the rapid advances that are being made in therapeutics and to expedite the drug acceptance procedure.

Meetings

The regular activities of the Council, including such matters as the consideration of products for acceptance and adoption of reports for publication, continue to be conducted through the medium of a biweekly confidential bulletin. However, the annual meeting of the Council provides an opportunity to discuss or review important problems relating to drug therapy, to consider modification or extension of activities and procedures, and to deliberate over the reports received from the various standing committees. During the meeting last year considerable time was devoted to a discussion of the problem of blood dyscrasias resulting from drug therapy and of possible means of mitigating this problem.

Correspondence

Most correspondence deals with matters relating to the drug acceptance program and the various publications issued or sponsored by the Council. In addition, several thousand inquiries from practicing physicians pertaining to drugs and therapeutics are answered by the Council office each year. Requests for information relating to particular drugs or therapeutic procedures are also received from numerous lay and professional groups or organizations. Many telephone inquiries are answered directly by the Council office staff.

Collaboration

Every effort is made to provide full collaboration with other groups or organizations on matters of mutual interest. Information is regularly exchanged between the Council office and the revision committee of the United States Pharmacopeia and National Formulary, the Federal Food and Drug Administration, and the United States Public Health Service. Information relating to the nomenclature as well as to the tests and standards for new drugs is also exchanged with groups or agencies in foreign countries. The program of collaboration with the revision committee of the International Pharmacopeia on the matter of selecting nonprotected names for new drugs has been continued. The Council supported the American drug industry in its criticism of the program involving the international adoption of nonproprietary names for drugs and aided in securing the adoption of an acceptable revised procedure in this regard. Not infrequently the Council office is also requested by other bureaus or departments at American Medical Association headquarters to furnish advice or assistance in matters involving drugs or therapeutics with which they are concerned.

Publications and Reports

New and Nonofficial Remedies, an annual publication of the Council, appeared in July of this year. N.N.R. contains information on the actions, uses, and doses of drugs accepted by the Council. The tests and standards for these products, which formerly appeared in N.N.R., have now been published as a separate volume, *Tests and Standards for New and Nonofficial Remedies.* This division of the book was undertaken so that information of greatest interest to physicians could be presented at minimum cost.

Fundamentals of Anesthesia, a complete revision of the 1944 edition, is now near the final stages of production and should be ready for distribution late in 1953. Manuscripts for the present edition were prepared by well-known anesthesiologists from various parts of the United States. The editorial task of integrating these manuscripts into the proposed style and outline of the book was supervised by a revision committee of prominent anesthesiologists in the Chicago area.

Glandular Physiology and Therapy, also completely revised, should be ready for publication early in 1954. All manuscripts are now in the hands of the publisher.

The Annual Reprint of the Reports of the Council on Pharmacy and Chemistry was published in a paper cover at Association headquarters this year and may be obtained directly from the Order Department.

Proceedings of the Second Conference on Steroids and Cancer, the complete minutes of the last meeting of the Subcommittee on Steroids and Cancer of the Committee on Research, has been lithographed and is available as a paper-covered volume from the Order Department at Association headquarters.

Committee on Pesticides

This is the fourth annual report of the Committee on Pesticides. The following activities were engaged in by the Committee during the past year in furtherance of its study program on the health hazards of pesticides and related materials.

Educational and Informational Projects.—The series of Committee reports reviewing medical and public health aspects of pesticidal chemicals has been extended to twelve with the publication in The Journal of statements on "Use and Abuse of Generic (Coined Common) Names for Pesticides"; "Toxicology in Medical Curriculum"; and "Health Problems of Vaporizing and Fumigating Devices for Insecticides: A Supplementary Report." Fifteen thousand reprints of these latest reports have been distributed to medical societies, public health and regulatory officials, and various other organizations and individuals in this country and abroad.

An exhibit entitled "Accidental Poisoning in Children" has been prepared by the office of the Committee. It illustrates typical fatal accidents in children due to drugs, household chemicals, and pesticides which were reported to the Committee office. The exhibit was originally presented at the Annual Meeting in New York in June, 1953, and has been subsequently displayed at the annual meeting of the American Pharmaceutical Association and the Cleveland Health Museum. A pamphlet prepared as a supplement to this exhibit has received wide circulation.

The first in a series of Outlines of Information on Pesticides have been developed by the Committee for use as aids in teaching. The outlines include a summary description of the pharmacological and toxicologic characteristics of various groups of pesticidal compounds, data sheets on individual pesticidal chemicals, and references to pertinent literature.

A Committee-sponsored radio transcription, "Defense Against Poisons," has also been prepared. The program, a 15 minute dramatization of typical cases of poisoning resulting from the careless use of agricultural or household chemicals, emphasizes the need for reading and heeding the directions contained on the label for such products. This transcription is available for use on radio programs sponsored by local medical societies.

A statement on the importance of including information on the pesticides in the pharmacology programs of medical and pharmacy schools was prepared by the Committee and presented at the annual meeting of the American Society for Pharmacology and Experimental Therapeutics.

Investigative and Research Projects.—The Committee office has been called on to implement a resolution adopted by the House of Delegates in December, 1951, concerning the accumulation and dissemination of information on potentially poisonous household chemical products. A compilation of trade names, composition, and labeling of widely distributed products in this category was undertaken during the past year. Reports of poisoning from mishandling, which appear in the literature or are on file at headquarters, are also being compiled. The Secretary represented the Committee at the Conference on Home Accident Prevention, University of Michigan, January, 1953, and on the American Standards Association's Committee on Hazards to Children.

Criteria for the evaluation of the safety of toxic substances for general use have been developed and adopted by the Committee on Pesticides. These criteria are presently being employed by the Committee as a yardstick on which the merits and potential hazards of a new compound or a novel method of application of an established substance may be measured. Toxicologic data and use factors are the basis for these criteria.

Studies involving the compilation and evaluation of cases of injury from pesticides were also continued. Accident reports were received from state and local health departments, industrial commissions, coroners and medical examiners, physicians in general practice, and other responsible sources. Special studies devoted to compiling cases of injury from insecticide residues, vaporizer chemicals, and organic phosphorus insecticides were begun or continued from the previous year.

Cooperative Projects.—The Committee continues to collaborate with other groups and organizations on problems of mutual concern. Technical information and other pertinent data was exchanged regularly with the California Department of Public Health, Federal Food and Drug Administration, United States Department of Agriculture, and United States Public Health Service. The Committee continued to serve as an advisory group to the Interdepartmental Committee on Pest Control in the selection of coined common (generic) names for pesticides. It adopted the Interdepartmental Committee rules for pesticides and mediated the consideration and adoption by the Council on Pharmacy and Chemistry of these rules which are in conformance with the basic principles employed by the Council for the selection of generic names for therapeutic substances. The Committee on Pesticides also cooperated with the Committee on Accident Prevention of the American Academy of Pediatrics in several areas of common interest. Liaison was maintained with other scientific groups and academic centers actively engaged in studies on pesticides.

Service Activities.—During the past year the Committee was asked by public and private agencies to consider and render opinion on a variety of medicoeconomic problems involving the hazardous potentialities of pesticides. Information and assistance were provided on many problems. Several hundred inquiries on the toxicity of pesticides and other chemicals in common use were answered by the Committee office staff. Assistance was provided various departments at Association headquarters in the preparation of book reviews and Queries and Minor Notes, and in the review of manuscripts and advertising on matters involving toxicology.

REPORT OF COMMITTEE ON RESEARCH

INVESTIGATIONS UNDER COMMITTEE-SPONSORED CONTRACTS

These investigations, while sponsored by the Committee on Research, have funds supplied to investigators by other agencies.

Investigation of Adjusted Ophthalmic Solutions.—The study of this problem was conducted under a grant from the American Pharmaceutical Association. The purpose of the investigation was to establish the clinical significance of the pH of ophthalmic solutions. The final report on this work was published in the *Journal of the American Pharmaceutical Association,* June, 1953.

Pendiomide.—The evaluation of this new ganglionic blocking agent in the induction of hypotension during surgery was undertaken at the Duke University School of Medicine with funds furnished by a grant from Ciba Pharmaceutical Products, Inc.

COOPERATIVE INVESTIGATIONS

The Committee on Research and its Subcommittee on Steroids and Hormones have arranged programs of research which pool the resources and experiences of large groups of investigators on specific research problems. Cooperative investigations of this type are particularly suited to such areas of research where single investigators cannot accumulate a sufficient number of cases annually to achieve statistical significance for their observations. By strict application of criteria for admission of cases to the study and by limitation of treatment to specified protocols, a relatively high degree of uniformity in diagnosis and treatment is secured for the data under analysis. Funds for support of the administration of these programs are furnished by the American Medical Association. The drug products utilized are supplied gratis by various pharmaceutical manufacturers. Further support is secured by the individual investigator from various granting agencies.

Influence of Steroid Hormones in Cancer.—The Subcommittee on Steroids and Hormones has continued into the sixth year studies of the influence of various hormones on inoperable cancer of the breast, genital organs, bladder, and bone. Thyroid cancer has been added to this group under observation during 1953. Compounds currently under investigation include TACE, methylandrostenediol, stanalone (dihydrotestosterone), and two long-acting testosterone esters, testosterone cyclopentyl propionate and testosterone phenyl propionate.

Investigation of Influence of Hormones on Pregnancy Complicating Diabetes Mellitus.—Scheduled for the fall of 1953 are a series of conferences of study groups of the Subcommittee on Steroids and Hormones to set up criteria for admission of cases and for the establishment of protocols for treatment of pregnancy complicating diabetes mellitus. A large group of obstetricians have evinced interest in this cooperative study. From preliminary estimates approximately 200 cases will be available for admission and analysis of data annually.

EDUCATIONAL AND INFORMATIONAL PROJECTS

During 1953 questionnaires relating to the extent of research activities have been distributed to a randomly selected list of 11,340 physicians. In addition, similar questionnaires were distributed to the military services, Public Health Service, Veterans Administration, medical schools, and pharmaceutical firms. This material will undergo analysis in the Committee office during the latter half of 1953 and early 1954.

Publications under auspices of the Committee include: Hypoplastic Anemias and Related Syndromes Caused by Drug Idiosyncrasy, Edwin E. Osgood, M.D., and Effects of Intensive Sex Steroid Hormone Therapy in Advanced Breast Cancer, B. J. Kennedy, M.D., and Ira T. Nathanson, M.D.

GRANTS-IN-AID

The establishment of the William Volker Fund extends the grants-in-aid program of the Committee on Research of the Council on Pharmacy and Chemistry into the basic medical sciences. When first organized as the Therapeutic Trials Committee, and, up to the present, fundamental objectives were to stimulate progress in the control and treatment of disease through facilitating investigations to establish the usefulness of diagnostic, preventive, and therapeutic agents. The William Volker Fund is not specifically restricted to grants in special fields such as heart disease, cancer, or hypertension. The Committee on Research feels that this is commendable, since the progress of medical research requires broad investigations in all fields of medical endeavor, including the basic sciences. This approach should furnish better understanding of the normal cell and organ functions than can be secured by research directed primarily to departures from the normal processes.

The Subcommittee on Grants-in-Aid has approved the following grants since Jan. 1, 1953. Listed after the grants for the current year are some grants of previous years made by the former Therapeutic Research Committee as well as by the Subcommittee on Grants-in-Aid in which an unexpended balance remains or the work is not yet completed.

Grant 75, $500.00 to Dr. Milton M. Ashley, University of Southern California, for study of localization of brain tumors and localization of intra-abdominal neoplasms.

Grant 76, $450.00 to Dr. Gordon H. Bryan, Montana State University, for assay of cardiotonic drugs by a chick embryo method, part II.

Grant 77, $500.00 to Dr. Morley Cohen, University of Minnesota, for experimental methods of intracardiac surgery under total venous inflow occlusion.

Grant 78, $500.00 to Dr. T. S. Danowski, University of Pittsburgh, for studies of steroid antagonists.

Grant 79, $350.00 to Dr. Calvin Hanna, University of Tennessee, for study of papaverine analogs as long acting coronary vasodilators.

Grant 80, $400.00 to Dr. Mervyn Gilbert Hardinge, College of Medical Evangelists, study time factor for inoculating tumors in animals fed potential antineoplastic agents.

Grant 81, $500.00 to Dr. Walter R. Hearn, Baylor University, for iodination of tyrosine peptides.

Grant 82, $250.00 to Dr. Walter C. Hess, Georgetown University, for stimulation of liver glycogen production by cortisone and other amino acids, in particular, glycine.

Grant 83, $350.00 to Dr. Julius B. Kahn Jr., University of Cincinnati, for the development of a method for the separation of veratrum alkaloids from biological tissues.

Grant 84, $500.00 to Dr. F. E. Kelsey, University of South Dakota, to study metabolism of selenium.

Grant 85, $500.00 to Dr. Matthew N. Levy, Union University, to study the effects of sympatholytic agents upon the peripheral vascular system.

Grant 86, $430.00 to Dr. Ernst Trier Morch, University of Chicago, for respiratory acidosis during anesthesia.

Grant 87, $350.00 to Dr. Wilhelm Raab, University of Vermont, to study the effect of sympatholytic drugs upon the pharmacodynamic activity of intrinsic myocardial norepinephrine and epinephrine.

Grant 88, $500.00 to Dr. Irwin H. Slater, University of Rochester, for the synthesis of drugs to control or eliminate spasticity following oral administration, division of pharmacological testing.

Grant 89, $500.00 to Dr. Jay A. Smith, Chicago Medical School, to study bronchoconstrictor effects of thiamine.

Grant 90, $500.00 to Dr. William M. Wallace, Western Reserve University, for the therapeutic evaluation of "BAL" and "Versene" in the clinical and experimental therapy of lead poisoning.

Grant 91, $500.00 to Dr. Nicolas T. Werthessen, Southwest Foundation for Research and Education, for the examination of relative potency as to specific pharmacological effects of various natural and synthetic estrogens.

Grant 92, $500.00 to Dr. William Q. Wolfson, Wayne University, for studies on methods and applications of paper electrophoresis and related techniques of possible value in clinical investigation.

Grant 93, $400.00 to Dr. Samuel B. Barker, Medical College of Alabama, to study the influence of thyroid hormone on enzyme systems.

Grant 94, $300.00 to Dr. Carmen Thomas Bello, Temple University, to study effect of veratum alkaloid (Veriloid) with serpentia on hypertensive patients.

Grant 95, $400.00 to Dr. Carl A. Dragstedt, Northwestern University, for studies on the cardiac glycosides.

Grant 96, $400.00 to Dr. Henry Earl Evert, State University of New York, to study the oxidation-reduction potential of thyroxine and related compounds and its relationship to biological oxidation.

Grant 97, $300.00 to Dr. Ernest Jawetz, University of California, for development of a simple test for bacterial sensitivity to antibiotic combinations, suitable for the clinical laboratory.

Grant 98, $300.00 to Dr. Kwang Soo Lee, Jefferson Medical College, to study the mechanism of action of digitalis principles.

Grant 99, $300.00 to Dr. Aaron Bunsen Lerner and Dr. Thomas B. Fitzpatrick, University of Oregon, to study the effect of low sulfur diets on psoriasis.

Grant 100, $350.00 to Dr. William T. Newsom, University of Oklahoma, for therapy of hyaline membrane disease of newborns and prematures.

Grant 101, $250.00 to Dr. Ralph W. McKeen, University of California, for growth and metabolic studies of Ehrlich's mouse ascites carcinoma cells.

Grant 102, $400.00 to Dr. J. Alfred Rider, University of California, to study cholinesterase activity in patients with peptic ulcer correlated with gastric secretory activity.

Grant 103, $375.00 to Dr. Wayne Rundles, Duke University, study of serum proteins in hemopoietic malignancies.

Grant 104, $300.00 to Dr. Clarence G. Sutherland, University of Arkansas, to study the effect of cortisone on ureteral intestinal anastomosis.

Grant 105, $400.00 to Dr. Daniel T. Watts, West Virginia Medical School, to study the effect of histamine and antihistaminic agents on respiratory resistance in guinea pigs.

Grant 106, $500.00 to the University of Louisville, to be divided between Dr. Joseph P. Holt for study of venomotor mechanisms in the regulation of arterial pressure and Dr. Peter K. Knoefel to study the pharmacology of the renal circulation.

Grant 107, $500.00 to the Michael Reese Hospital Research Institute to be divided between Dr. Simon Rodbard for frequency analysis of heart sounds and murmurs and Dr. Herta Sorter to study blood chemistry in the aged.

Grant 108, $600.00 to the University of Texas to be divided between Dr. Marian L. Cramer for studies on the mode of action of streptomycin and Dr. Lothar L. Salomon for studies on ascorbic acid and cholesterol: Their metabolic fate under conditions of "Stress."

Grant 109, $800.00 to the University of Washington to be divided between Dr. John L. Bakke to study adrenal-thyroid relationships, Dr. Donald F. McDonald for experimental nonhormonal chemoinhibition of the mammalian prostate: II. human benign prostatic tumors, and Dr. H. W. Youngken Jr. for the production of labelled digitalis glycosides in digitalis purpurea by the use of C^{14} carboxyl labelled sodium acetate.

Grant 110, $350.00 to Dr. Arnold D. Welch, Yale University, to investigate the significance of the carboxyl group of orotic acid in the biosynthesis of pyrimidine-containing nucleotides.

Grant 111, $500.00 to Dr. Margaret Q. Jenkins, Medical College of South Carolina, to study glomerulonephritis in sickle cell anemia.

Grant 112, $400.00 to Dr. Charles Weiss, Albert Einstein Medical Center, to investigate the mechanism of caseation and softening in experimental tuberculosis of rabbits.

Grant 113, $500.00 to Dr. Miriam E. Simpson and Dr. Gertrude Van Wagenen, University of California and Yale Medical School, to study the effect of gonadotrophins in immature male and female Macaca mulatta.

Grants from the Brant Fund:

Brant Grant 3, $350.00 to Dr. G. J. Tarleton Jr., Meharry Medical College, for studies on irradiation injury in mice; protection of mice against x-irradiation.

Brant Grant 4, $350.00 to Dr. William H. Olson, Medical Research Institute of Michael Reese Hospital, to investigate primary depression by insulin of gastric secretion in normal man.

Grants issued before Jan. 1, 1953:

Grant 408, $300.00 to Ephraim Shorr, Cornell University Medical College, the effect of progesterone on the vaginal smear.

Grant 454, $50.00 to W. L. Mendenhall and Albert J. Plummer, Boston University, the quantitative determination of theophylline.

Grant 455, $100.00 to Frederick H. Pratt and Marion A. Reid, Boston University, the effect of cardiac drugs on the denervated lymphatic heart.

Grant 499, $200.00 to Joseph Litwins, New York Medical College, the chemistry and hematology of blood donars.

Grant 506, $600.00 to Andrew F. Burton, Howard University, (1) the distribution of sulfanilamide in maternal and fetal tissues at various stages of pregnancy and (2) the toxic effects of quinine on the fetus in utero.

Grant 561, $400.00 to G. L. Cantoni, Long Island College of Medicine, the mechanism whereby potassium exerts its effect on the intact smooth muscle.

Grant 572, $1,000.00 to C. H. Werkman, Iowa State College Department of Bacteriology, the mechanism of action of penicillin and streptomycin.

Grant 575, $1,000.00 to E. Barrett, L. J. Poo, L. Way and W. Yuen, Stanford University School of Medicine, reasons for the differences in the effects of various proteins on the rate of growth of the kidney.

Grant 586, $500.00 to Harold D. Green, Wake Forest College, Bowman Gray School of Medicine, the role of the liver and kidneys in shock.

Grant 587, $500.00 to Richard C. de Bodo, New York University, the antidiuretic action of some depressants of the central nervous system.

Grant 603, $500.00 to Joseph H. Cort, Yale University, the effects of chronic stimulation of the autonomic nervous system of normal unanesthetized animals.

Grant 607, $200.00 to Boyd Houchin, University of Louisville, the qualitative estimation and differentiation of tocopherols in blood of patients with congestive heart disease before and after the parenteral administration of dl-alphatocopheryl phosphate.

Grant 612, $500.00 to J. Lerman, Massachusetts General Hospital, therapeutics of hyperthyroidism.

Grant 613, $400.00 to Eugene P. Pendergrass and Harry P. Schenck, University of Pennsylvania, the effects of radiation on the lymphoid tissue of the human nasopharynx.

Grant 614, $500.00 to Richard C. de Bodo, New York University, the mechanisms of insulin hypersensitivity.

Grant 618, $500.00 to T. T. Chen, State Teachers College, Bemidji, Minn., an antibiotic substance which may have therapeutic value with respect to protozoan diseases.

Grant 622, $750.00 to Lester M. Morrison, College of Medical Evangelists, the role of lipoid metabolism in the pathogenesis of coronary artery thrombosis and in atherosclerosis of human subjects.

Grant 624, $265.00 to S. W. Clausen, University of Rochester, influence of coconut milk on the growth and utilization of vitamin A by the rat.

Grant 627, $500.00 to Janet W. McArthur, Massachusetts General Hospital, adrenal cortical function in diabetic acidosis.

Grant 631, $300.00 to C. P. Kraatz, Jefferson Medical College of Philadelphia, to determine in dogs whether pyridoxine will antagonize the vomiting induced by various types of drug stimulation.

Grant 632, $500.00 to E. B. Carmichael, Medical College of Alabama, meperidine (Demerol) hydrochloride.

Grant 634, $500.00 to M. H. F. Friedman, Jefferson Medical College of Philadelphia, experimental therapy of nonspecific ulcerative colitis.

Grant 636, $500.00 to R. R. Overman, University of Tennessee, mechanisms of ionic imbalance in malaria and associated pathophysiological states.

Grant 638, $500.00 to A. H. Schein, University of Vermont College of Medicine, uric acid levels in humans.

Grant 641, $500.00 to Joseph B. Kirsner, Walter L. Palmer, and William E. Ricketts, University of Chicago, hepatic disease.

Grant 642, $500.00 to Robert C. Lowe, University of Oklahoma, hepatic metabolism.

Grant 644, $500.00 to Albert Milzer, Michael Reese Hospital, a survey of virus and rickettsial infections in Chicago.

Grant 645, $400.00 to Stuart Mudd, University of Pennsylvania, the cytology of normal and phage-infected cells.

Grant 646, $500.00 to T. T. Chen, University of Southern California, antibiotics produced by protozoa, especially Paramecium, to determine their possible therapeutic value.

Grant 647, $500.00 to Irving Siegel, Chicago Medical School, the difference, if any, in the healing of incisions in the pregnant and nonpregnant uterus.

Grant 648, $500.00 to Emmett J. Carmichael, W. H. Johnson and F. A. Key, Medical College of Alabama, toxicity of meperidine (Demerol) hydrochloride.

Grant 652, $500.00 to Robert C. Grauer, Allegheny General Hospital, Pittsburgh, sex hormones in mammary cancer.

Grant 653, $250.00 to Harald Holck, University of Nebraska Foundation, liver and detoxification of Nostal in the rat.

Grant 655, $500.00 to S. W. Britton, University of Virginia, adrenal glands in maintaining upright position.

Grant 657, $500.00 to R. Beutner, T. C. Barnes and Jens Christiansen, Hahnemann Medical College, (1) drugs and skin healing, (2) toxicity of cardiac drugs and (3) Antabuse in alcoholism.

Grant 658, $400.00 to Joseph B. Kirsner, William E. Ricketts, and Walter L. Palmer, University of Chicago, studies on hepatic disease.

Grant 659, $400.00 to John B. Lambooy, University of Rochester, synthesis of 2,3- and 2,6- and 3,5-dihydroxy-phenylalanines.

Grant 2, $500.00 to Percival Bailey, University of Illinois, to investigate stereotoxic apparatus for use on human brains.

Grant 3, $200.00 to Sumner Kalman, Stanford University, to investigate the prolongation of inhibitory effects of steroids on neoplasms.

Grant 5, $200.00 to Joseph R. DiPalma, Hahnemann Medical College and Hospital, to compare the effects of various compounds against quinidine for anti-fibrillatory potency to determine if an effective substitute for quinidine can be found.

Grant 6, $400.00 to Theodore Koppanyi, Georgetown University, to evaluate the effects of intravenous injections of cholinesterases.

Grant 8, $250.00 to James C. Rice, University of Mississippi, to determine the effect of sodium ferricyanide as an antagonist to the action of certain musculotropic poisons.

Grant 9, $500.00 to Miriam E. Simpson and Gertrude Van Wagenen, University of California and Yale University, to study the pituitary gonadotropins in the Rhesus monkey (Macaca mulatta).

Grant 10, $500.00 to Clinton H. Thienes, University of Southern California, to study the effect of nicotine on the metabolism of the brain.

Grant 11, $500 to Harold C. Wiggers, Union University, Albany Medical College, to investigate the production and study of mitral stenosis and/or insufficiency by insertion of substitute plastic valves in dogs hearts.

Grant 12, $200.00 to Alan D. Bass and Henry DiStefano, State University of New York, to investigate alterations in tissue nucleoprotein patterns following administration of therapeutic agents (e. g. morphine, insulin, colchicine).

Grant 13, $400.00 to Edward L. Corey, University of Virginia, the electromyographic study of the human urinary bladder.

Grant 14, $400.00 to T. S. Danowski, University of Pittsburgh, the exploration of the mechanical characteristics and the clinical utility of the Alwall-type artificial kidney.

Grant 15, $400.00 to Andres Goth, Southwestern Medical School of the University of Texas, the experimental reevaluation of analeptics in the treatment of barbiturate intoxication.

Grant 16, $400.00 to A. Clark Griffin, Stanford University, to investigate the alleviation of the symptoms of nitrogen mustards by cystein and thiourea.

Grant 17, $400.00 to Keith S. Grimson, Duke University, to investigate the treatment of aneurysms of the aorta.

Grant 18, $400.00 to Howard L. Holley and James S. McLester, University of Alabama, to investigate potassium intoxication in cardiorenal diseases as a result of using salt substitutes.

Grant 19, $350.00 to Gene Frederick Lata, State University of Iowa, to investigate panthothenic acid and the biosynthesis of cholesterol.

Grant 21, $200.00 to Ethan A. H. Sims, University of Vermont, for studies on the inactivation of adrenal cortical steroids by the rat liver.

Grant 22, $300.00 to Hans Selye, Institute of Experimental Medicine and Surgery Montreal University, to study the pituitary factor which influences barbiturate detoxification.

Grant 23, $300.00 to Thomas G. Morrione, Long Island College Hospital, Brooklyn, N. Y., to investigate alterations in blood glycogen in hepatic disease.

Grant 24, $500.00 to Edward L. Maxwell, Alabama State College for Negroes, to investigate production of androgen by the testes of fetuses.

Grant 25, $400.00 to Dr. Herbert L. Borison, University of Utah, to study the site of emetic action of veratrum alkaloids.

Grant 26, $400.00 to Dr. Clyde W. Phillips, Howard University, to study the effect of steroid hormones on the Mann-Williamson ulcer.

Grant 27, $500.00 to Dr. G. J. Tarleton Jr., Meharry Medical College, for permeability studies on irradiated mice; protection of mice against x-irradiation.

Grant 28, $500.00 to Dr. Harold G. Grayzel, Jewish Hospital of Brooklyn, to study the effect of ACTH and cortisone upon the production of amyloidosis.

Grant 29, $300.00 to Dr. Jens A. Christensen, Hahnemann Medical College, to investigate experimental chemotherapeutic tumor response in animals after pretreatment with arginase.

Grant 30, $300.00 to Dr. Robert H. Dreisbach, Stanford University, to investigate treatment of poisoning from agricultural chemicals.

Grant 32, $250.00 to Dr. Walter C. Hess, Georgetown University, to investigate stimulation of liver glycogen production by cortisone and glycine.

Grant 33, $500.00 to Dr. Alfred G. Lisi, Jefferson Medical College, to study the effect of surface active agents (detergents) on nerves as regards impulse transmission and demarkation potential.

Grant 34, $500.00 to Dr. M. Jane Oesterling, Woman's Medical College of Pennsylvania, to investigate oxidation-reduction reactions influenced by ascorbic acid.

Grant 35, $500.00 to Dr. Stelios C. Samaras, Creighton University, to investigate narcosis and detoxication in relation to reticuloendothelial system.

Grant 36, $500.00 to Dr. Ralph I. Dorfman, Worcester Foundation for Experimental Biology, to investigate metabolism of adrenal cortical steroids by liver tissue.

Grant 37, $500.00 to Dr. Robert W. Heinle, Western Reserve University, for clinical and experimental evaluation of ACTH and cortisone in hematopoitic disorders.

Grant 38, $350.00 to Dr. Ludwik Anigstein, University of Texas, to investigate the effect of cortisone and ACTH on murine bartonellosis and experimental rickettsial infections.

Grant 39, $300.00 to Dr. T. S. Danowski, University of Pittsburgh, to investigate enhancement of the efficiency of the Alwall type artificial kidney.

Grant 40, $300.00 to Dr. Leonard P. Eliel, Oklahoma Medical Research Institute and Hospital, for a study of the mechanism of action of various agents which alter the growth rate of tumor in man.

Grant 41, $300.00 to Dr. George A. Hellmuth, Loyola University, for studies of the formation of spatial vectrocardiographic loops in relation to direct and indirect electrocardiography.

Grant 42, $250.00 to Dr. Howard L. Holley, Medical College of Alabama, for the study of electrolytes in synovial fluid in the normal and arthritic joint.

Grant 43, $400.00 to Dr. Julius B. Kahn Jr., University of Cincinnati, to investigate effects of 2, 3-dimercaptopropanol (Dimercaprol) in the metabolism and effects of barbiturates.

Grant 44, $200.00 to Dr. Kazuo K. Kimura, St. Louis University, to investigate structure-activity relationships of synthetic compounds which possess curare-like action on striated muscles.

Grant 45, $250.00 to Dr. David Lehr, New York Medical College, to investigate sulfonamide mixture therapy.

Grant 46, $250.00 to Dr. James W. Mankin, Bowman Gray School of Medicine, to investigate the effect of gastric acidity on the absorption of quinidine sulfate from the gastrointestinal tract.

Grant 47, $350.00 to Dr. Lester M. Morrison, College of Medical Evangelists, to investigate dietary treatment of coronary atherosclerosis.

Grant 48, $450.00 to Dr. Benjamin De Boer, University of North Dakota, to investigate the action of morphine antagonists on the hyperglycemia produced by morphine and morphine-like compounds.

Grant 49, $300.00 to Dr. Irwin MacKay Murray, State University of New York, to study a method for the quantitative biological assay of adrenal cortical hormones.

Grant 50, $300.00 to Dr. Hugh J. McDonald, Loyola University, to investigate ionographic separation and study of blood plasma constituents.

Grant 51, $250.00 to Dr. R. H. Rigdon, University of Texas, to investigate effect of B_{12} on selenium poisoning in rats.

Grant 52, $300.00 to Dr. Hilton A. Salhanick, University of Utah, to study separation and characterization of a potentiating substance for progesterone.

Grant 53, $300.00 to Dr. Leo A. Sapirstein, Ohio State University, to investigate d-l amphetamine in treatment of edema.

Grant 54, $350.00 to Dr. George H. Scherr, Creighton University, to investigate the effect of gonadotropic hormones on systemic histoplasmosis in mice.

Grant 55, $250.00 to Dr. Lawrence J. Schroeder, Wayne University, for studies on lathyrism.

Grant 56, $300.00 to Dr. Lloyd D. Seager, University of Arkansas, for a study of the sensitivity to ultraviolet light produced by stilbamidine.

Grant 57, $300.00 to Dr. Stuart W. Smith, University of Colorado, for studies on the functional relationship between the neurohypophysis and the anterior lobe of the hypophysis.

Grant 58, $500.00 to Dr. John H. Lamb, Oklahoma Medical Research Foundation, for the investigation of a group of steroids as antifungal agents.

Grant 59, $400.000 to Dr. Klaus R. Unna, University of Illinois, to investigate action of curarizing agents in myasthenia gravis.

Grant 60, $350.00 to Dr. John Franklin Van Pilsum, University of Utah, to investigate the inhibition of uricase by xanthine.

Grant 61, $300.00 to Dr. Arnold D. Welch, Western Reserve University, to investigate the significance of the carboxyl group of orotic acid in the biosynthesis of pyrimidine-containing nucleotides.

Grant 62, $200.00 to Dr. R. W. Whitehead, University of Colorado, for a study of the effects of ACTH, of cortisone, and compound F on the course of poisoning by botulinus and diphtheria toxins.

Grant 63, $300.00 to Dr. Hans H. Zinsser, University of Southern California, for quantitation of sulphur containing amino acids in cystinuria by automatic sample collector purchase.

Grant 64, $400.00 to Department of Pharmacology, Hahnemann Medical College to be divided among Dr. T. C. Barnes to study the effect of drugs on the electroencephalogram of animals during activation by flashing light and Dr. Benjamin Calesnick to study factors influencing cardiac conduction.

Grant 65, $700.00 to the University of Washington, to be divided between Dr. John L. Baake, for the study of adrenal-thyroid relationships and Dr. Frederick Wirth Maire, to study hemorrhagic pulmonary edema produced by hypothalamic lesions.

Grant 66, $390.00 to Dr. J. C. Hayner, New York Medical College, for a preliminary study on the feasibility of building reserves of fetal endocrine material for future implantation.

Grant 68, $500.00 to Dr. Miriam E. Simpson and Gertrude Van Wagenen, University of California and Yale University, to study the effect of gonadotrophins in immature male and female Macaca mulatta.

Grant 69, $500.00 to Dr. Stewart C. Harvey, University of Utah, to study the interrelationships of cardiac glycosides and actions and the effects of cations on digitoxin uptake of the heart.

Grant 70, $400.00 to Dr. Robert I. Lowenberg, Yale University, for ureteral segments used as arterial grafts.

Grant 71, $500 00 to Dr. Edwin Sinaiko, Michael Reese Hospital, Medical Research Institute, for the formation of an artificial bladder.

Grant 72, $500.00 to Dr. Julius Pomeranze, New York Medical College, for blood volume studies in geriatric subjects.

Grant 73, $500.00 to Dr. Lawrence H. Rubenstein, Michael Reese Hospital, for repair of esophageal defects with skin transplants.

Grant 74, $500.00 to Dr. Allan Hurst, National Home for Jewish Children, to study the effect of intermittent positive pressure breathing, and breathing exercises on pulmonary function of the asthmatic child.

Brant Grant 1, $500.00 to Dr. Martin Silberberg, Snodgras Laboratory Hospital division, City of St. Louis, 'Washington University Medical School, to investigate the growth of the mammary gland and hemopoietic tissues in mice receiving grafts of anterior hypophyses, ovaries, and adrenals.

Brant Grant 2, $500.00 to Dr. Sydney William Britton, University of Virginia Medical School for studies of adrenal involvement in maintenance of the upright position.

Following is a list of the investigations conducted with the assistance of grants made by the Committee on Research, reports of which were published:

From an anonymous contributor grants were directed through the Committee on Research to the Instituto-Nacional-de-Cardiologia, Mexico D. F., Mexico, $1,745.00, and to the Robert Miller scholarship fund, $1,500.00.

Report of Committee on Cosmetics

This is the fourth annual report of the Committee on Cosmetics. During the past year, the Committee continued to encourage the scientific approach in the formulation and manufacture of cosmetics through proper quality controls and thorough laboratory and clinical investigation of new products. The essential medium for implementing this aim is the Committee's evaluation program for cosmetics and allied preparations. All products are evaluated on the basis of data on composition, safety, manufacturing controls, and advertising claims. At the Committee's direction, toxicity and actual use data may also be required. Recently revised copies of the Committee's rules are available on request.

A number of products have been submitted to the Committee during this year for consideration and have successfully met the requirements for acceptance. The majority of these products are regular cosmetic items, while a smaller proportion include cleansing agents, baby products, and industrial protective creams. Descriptive statements of these products are published in the report on accepted products in The Journal. Accepted products are privileged to display the seal of the Committee, which is similar in design to the seals of the scientific councils of the American Medical Association. A pamphlet listing all accepted products is under preparation for general distribution.

Another primary aim which this year's activities continued to foster is the promotion of a better understanding among the medical profession and the public of the true usefulness of cosmetics tempered with a knowledge of their limitations. Particular emphasis is given to those cosmetics which under some circumstances can be harmful. Manufacturers as well as users are urged to exercise proper precautions to insure maximum safety and usefulness.

The dissemination of pertinent information to the medical profession and the public is accomplished through the various mediums available for this purpose. Reports on timely subjects in the cosmetic field are authorized for publication in The Journal and *Today's Health*. An extensive inquiry service conducted by the Committee office staff also serves as an instrument for education. The majority of letters come from practicing physicians and the general public on matters of safety and usefulness. A large portion of the remaining correspondence comes from personnel of firms manufacturing or distributing cosmetics and allied preparations.

As in other years, there has been close cooperation between the Committee and organizations such as Better Business Bureaus, the Federal Trade Commission, the Food and Drug Administration, and newspaper and magazine editors. The Committee also functions in an advisory capacity to the Council on Pharmacy and Chemistry, the Advertising Committee, the Public Relations Department, the Editorial Department, and other groups within the Association where problems of mutual interest exist.

Report of American Medical Association Laboratories

CHEMICAL SECTION

EXAMINATION OF DRUGS FOR ACCEPTANCE BY THE COUNCIL ON PHARMACY AND CHEMISTRY

As in the past years most of the time and effort of the Chemical Laboratory's personnel was directed toward the chemical examination of products presented to the Council on Pharmacy and Chemistry in its acceptance program. The Laboratory's part in the program is to check the drugs for identity, quality, purity, and potency. In the case of products which are new and will be available on the market for the first time, the Laboratory establishes tests for identity, purity, and potency to which these drugs must conform as a part of the Council's acceptance program. Tolerances are established. These tests and standards are incorporated in monograph form and published in THE JOURNAL as portions of the reports of the Council on Pharmacy and Chemistry. At the end of the year the new monographs are incorporated with other standards established in previous years for new and nonofficial drugs. This past year, for the first time, the tests and standards have been published in a volume separate from New and Nonofficial Remedies. The book is entitled "Tests and Standards for New and Nonofficial Remedies." During the past year 248 presentations were referred to the Chemical Laboratory by the Council. There were 530 individual items under consideration. Tests and standards monographs were established for 30 new drugs and the 49 dosage forms into which they were incorporated.

The Chemical Laboratory staff continued in its advisory capacity to the Council on Pharmacy and Chemistry in regard to nomenclature and the technical aspects of pharmacy and chemistry. The Laboratory cooperated closely with the Committee on Publications of the Council in the publication of both "New and Nonofficial Remedies" and the separate volume "Tests and Standards for New and Nonofficial Remedies."

THE COSMETIC PROGRAM

Cooperation with the Committee on Cosmetics in its program of cosmetic acceptance has continued as in past years. Twenty-eight products have been considered from the chemical view. Comments concerning control procedures have been forwarded to the Committee. Opinions concerning the actions and claims made for the preparations have been referred to the Committee for whatever action it deemed advisable.

COOPERATION WITH OTHER DEPARTMENTS OF THE ASSOCIATION

The Chemical Laboratory has had occasion during the past year to examine products at the request of the Bureau of Investigation, the Council on Foods and Nutrition, and the Advertising Committee. It has continued to help the Editorial Department in regard to chemical and technical statements which appear in articles for publication in THE JOURNAL. It has assisted the Library in the classification of chemical and technical nomenclature for the Quarterly Cumulative Index Medicus. It has advised the Advertising Committee at its request concerning technical statements on advertising copy and on occasion has examined products on its behalf.

SPECIAL PROBLEMS

The Laboratory is continuing its study of cigarettes, cigarette smoke, and filters which was initiated at the request of the Advertising Committee. Two articles were published in THE JOURNAL during the past year, one on filter-tip cigarettes and the other on low-nicotine content cigarettes. Work continued in attempting to improve analytical methods and techniques concerned with the chemical problems of products under consideration in the Laboratory.

The Laboratory has answered many letters of inquiry from the medical profession concerning those technical matters which the Laboratory's personnel is qualified to consider and in several instances has contributed to Queries and Minor Notes. It has reviewed for THE JOURNAL about 25 books during the past year mostly of a chemical nature but in most instances bearing on the field of medicine.

MICROBIOLOGIC SECTION

Since its inception in 1950, the Microbiologic Laboratory has continued to enlarge its activities with a view to a comprehensive program of microbiologic tests and standards.

The Laboratory has examined approximately 130 products submitted for inclusion in New and Nonofficial Remedies. Sterility tests were conducted on samples of these products in accordance with the methods prescribed by the U. S. Pharmacopeia XIV and by the U. S. Food and Drug Administration, as well as by other methods especially applicable to the substances under consideration. In addition, procedures for the determination of antibacterial activity were employed in those instances where such claims were made by the manufacturer. A program for testing the potency of those antibiotics not certified by the Food and Drug Administration is now under way.

Special problems submitted by other departments of the Association have also been investigated in the Laboratory. These include bacteriological examination of food products, evaluation of laboratory equipment, determination of the efficacy of devices used in hospital sterilization procedures, and classification of streptococci. The Microbiologic Laboratory has served the Council on Pharmacy and Chemistry in the preparation of reports for the Council Bulletin, and in the revision of sections in "New and Nonofficial Remedies." Numerous inquiries on bacteriological problems from physicians and the lay public have also been answered. In addition, assistance has been given to various departments and Councils of the Association in evaluating microbiological data submitted in connection with advertising and presentations of products. As in the past, publications in the field of microbiology have been reviewed for the Library.

The Microbiologic Laboratory has as one of its functions the examination and evaluation of sterilization procedures submitted in presentations of pharmaceutical products for Council acceptance. The evaluation of so-called marginal methods of sterilization employed for heat-labile products is a problem which has been of particular concern, since at present there are no adequate test procedures available. A program for formulating such test methods has been initiated. A tentative guide for the determination of the adequacy of "marginal" processings has been drafted and distributed to manufacturers, official agencies, and other interested parties. It is recognized that, in order to arrive at a test procedure which will be bacteriologically sound as well as practical for the manufacturer, further revision of the tentative guide is necessary. To this end, the Laboratory held a conference in August during the convention of the Society of American Bacteriologists in San Francisco. Representatives of the pharmaceutical and canning industries as well as authorities from various academic institutions participated in this meeting. The criticisms and suggestions offered will form the basis for further investigative work.

Report of Council on Physical Medicine and Rehabilitation

PUBLICATIONS

The Council published the following articles in THE JOURNAL: "Power Output of Diathermy Apparatus," "An Appreciation" in which the Council expressed its appreciation to consultants who had contributed their services, "Calculators for Applying the Ogino-Knaus Theory," the "Miracle Hearing Aid," and "Minimal Requirements for Acceptable Speech Audiometers." In addition, a pocket-sized instruction card entitled "Artificial Respiration" was printed and widely distributed. The 1953 edition of "Apparatus Accepted by the Council on Physical Medicine and Rehabilitation" is scheduled for release in October.

COUNCIL ADVISORY COMMITTEES

American Health Resorts.—The Advisory Committee on American Health Resorts has continued its consideration of those institutions requesting listing by the Council. During the course of the year, one American health resort center was visited by a member of the Advisory Committee and the secretary of the Council to discuss problems related to providing adequate medical supervision.

Audiometers and Hearing Aids.—The Advisory Committee on Audiometers and Hearing Aids held its annual meeting in August, and representatives of manufacturers of hearing aids and audiometers also attended a portion of this meeting. A representative of one of the manufacturers of transistors, now being used in hearing aids, presented a technical discussion on their manufacture and application. The Committee reviewed the progress of its Subcommittee, which is formulating a revision in the procedure for evaluating the percentage loss of hearing. This activity has been carried over from the previous year, and because of the many technical questions that have arisen in connection with this problem, continued study will be necessary before a satisfactory revision can be formulated. Twelve hearing aids and three audiometers were submitted to the Council for acceptance during the year.

Education.—Because the fostering of the proper use of various apparatus and methods in medicine that had a physical basis for their action necessitated educational activities directed toward physicians and lay therapists, the Council established a Committee on Education in 1925. The Council has continued its interest in physical therapy education, particularly since 1929 when the American Physiotherapy Association requested the Council to inspect, evaluate, and accept schools of physical therapy. Although the Council declined in 1929 to undertake the inspection and acceptance of schools of physical therapy, it did work with the Council on Medical Education and Hospitals and other interested parties to the end that in 1936 the Council on Medical Education and Hospitals assumed this activity, published essentials for the acceptance of such technical schools, and initiated an approval program.

The Council on Physical Medicine and Rehabilitation, with the aid of its Advisory Committee on Education, has thus continued its interest in education of physical therapists and occupational therapists and has continued, at the request of the Council on Medical Education and Hospitals, to consult with that Council regarding course requirements for the training of such personnel. The Council submitted a proposed revision of the Essentials of an Acceptable School of Physical Therapy to the Council on Medical Education and Hospitals during the year.

Electrocardiographs.—Two electrocardiograph devices were submitted to the Council for acceptance. The Committee has continued its consideration of minimal requirements for the acceptance of vectorcardiograph apparatus.

Ophthalmic Devices.—The Advisory Committee on Ophthalmic Devices has assisted the Council in the consideration of two such apparatuses submitted during the year, and has advised the Council regarding various special ophthalmic devices which do not come within the purview of the acceptance program but which are advertised in American Medical Association publications.

Respirators.—The Advisory Committee on Respirators has assisted in the consideration of various respiratory devices submitted to the Council. It has advised the Council in relation to manual artificial respiration methods, and members of the Advisory Committee have participated in the Council exhibit on that subject, which has appeared at a number of medical meetings throughout the country during the year.

Sterility and Fertility.—An article on "Calculators for Applying the Ogino-Knaus Theory" was promulgated by this Advisory Committee, accepted by the Council, and published in THE JOURNAL this year. Another article pointing out the dangers inherent in the use of certain types of stem pessaries was also prepared under the auspices of this Advisory Committee and recommended to the Council for acceptance and publication.

Ionizing Radiations.—The Council and its Advisory Committee on Ionizing Radiations has been concerned over the potential hazards involved in the use of x-ray apparatus in the fitting of shoes. The Committee is attempting to collect data in order to compile and publish a report on this subject.

Physical Laboratory

Most of the work of the Physical Laboratory has come under the following headings: (1) preliminary physical description of all apparatus submitted by manufacturers for consideration by the Council; (2) more detailed examination of the construction and physical performance of particular types of submitted apparatus; and (3) inspection of some kinds of apparatus that do not come within the purview of the Council but require critical appraisal for the purposes of other councils or committees. The first category of 20 items included apparatus like audiometers that must be sent on to other more specialized laboratories. The second category of 71 items reflected especially the current interest in generators for stimulating muscles and nerves and apparatus for applying shocks to the asystolic or fibrillating heart. The third category of 6 items ranged from microscopes to pasteurizers.

The laboratory staff has begun the statistical study of certain audiometric data needed in the revision of the American Medical Association method of scoring impairment of hearing. The laboratory has also proved useful in preparing scientific exhibits such as that on medical uses of the transistor and radioactive materials.

Other Activities

Because of certain information regarding gas pressures which should be available in resuscitators, the Council again reviewed its minimal requirements for the acceptance of resuscitators and inhalators, with physicians and other scientists in the field, as well as the manufacturers of such devices.

The introduction of ultrasonic generators for use in therapy has been noted by the Council. One such device has been submitted to the Council for consideration for acceptance. The Council is currently collecting data in order to compile a statement for publication on this physical agent.

Approximately 68 pieces of apparatus were submitted to the Council in 1953 for consideration for acceptance. Thirty pieces of apparatus were reported on in THE JOURNAL as accepted.

Report of Council on Foods and Nutrition

The Council on Foods and Nutrition, now completing its 24th year as an integral part of the American Medical Association, has continued to play an important role in shaping progressive policies in food and allied industries and in publishing sound nutritional information for both the physician and the layman. The seal of the Council appearing on special purpose foods and in advertising is mute testimony to the fact that such foods and advertising have been critically examined by the Council; that the Council has been apprised of the manufacturing process employed; that the Council considers the food to be wholesome and useful for its stated purpose; and that claims made are in keeping with the latest scientific evidence or the best available scientific opinion.

Food Acceptance and Advertising

The vastly increased interest in foods prepared for use in diets of restricted sodium content has occupied a large portion of the Council's time. Many brands of vegetables packed without added salt have been submitted to the Council and accepted. Certain vegetables having a relatively high natural sodium content were deemed to be unsuitable for use in sodium-restricted diets even though no salt was used in processing them. Because of the meager information available concerning the natural sodium content of vegetables, the Council has secured the cooperation of the packers concerned in making an extended study of the variations to be expected in sodium content. The accumulation of such data will enable the products to be labeled accurately so that the physician will be able to incorporate them with confidence in the diets of his patients requiring a restricted sodium intake. The production of foods for use in sodium-restricted diets presents some problems that have yet to be solved. For instance, the removal of most of the sodium from milk also results in significant reductions in the amounts of various other essential nutrients present in milk. Such a product can no longer be called milk, and the Council is justifiably concerned with its labeling and advertising.

The publicity given to the prevalence of overweight in the country has resulted in an overwhelming interest on the part of the public and the food processors in foods specifically designed for use in calorie-restricted and carbohydrate-restricted diets, particularly those containing non-nutritive artificial sweetening agents. Because of the great number of proposed uses for artificial sweeteners in processed foods, a special meeting was held on April 9, 1953, at which members of the industry presented their views to the Council and a group of consultants. After due deliberation, the Council decided to include within its acceptance program artificially sweetened canned fruits and certain other artificially sweetened foods. The Council will not consider a product for acceptance merely because it happens to contain an artificial sweetener instead of sugar. The product must have nutritional merit and be useful. Also the Council emphasized the fact that artificially sweetened foods are for use only in special diets and should not be used indiscriminately.

The acceptability of foods containing sorbitol and mannitol for use in calorie-restricted and carbohydrate-restricted diets is still under consideration, but as of this date no sound nutritional reason is seen for the incorporation of these substances in such foods.

The Council continued to examine for acceptance new submissions of strained and chopped infant foods and other eligible special purpose foods, as well as vitamin D fortified milks from dairies all over the country. Advertising copy for accepted products and educational advertising continued to be critically examined. Apparently educational advertising is being used more and more extensively as various food processors and trade organizations are discovering its effectiveness. The Council's well known prestige in the field of nutrition has resulted in excellent cooperation from all parties concerned—manufacturers, distributors, and trade organizations, and their advertising agencies.

COUNCIL REPORTS

The Council requested several authorities in the field of nutrition to write articles on certain aspects which it was felt were of popular interest to both the physician and his patients. These articles were all reviewed by the Council and are being published in THE JOURNAL as Reports to the Council.

Four articles already published and the issue of THE JOURNAL in which they appeared are as follows: "Physical Medicine and Obesity," Jan. 24, 1953; "Nutrition of Athletes," March 7, 1953; "Disaster Feeding," April 18, 1953; and "Trends and Needs in Nutrition," May 2, 1953. Three additional articles that have been reviewed by the Council are scheduled for publication in THE JOURNAL at an early date. One is entitled, "The Story of Kwashiorkor"; another, "Trace Elements in Brucellosis"; and the third, "The Psychiatric Aspects of Obesity."

GOLDBERGER AWARD

Dr. William H. Sebrell, director of the National Institutes of Health, received the third Joseph Goldberger Award in Clinical Nutrition at a dinner of the Council in December, 1952. This award is presented annually on recommendation from the Council for outstanding and sustained work in the field of clinical nutrition. It consists of a gold medal and $1,000 made possible by a grant from the Nutrition Foundation. Dr. Sebrell's exceptional work in the field of riboflavin deficiency and pellagra prevention with Dr. Goldberger, along with his long-continued work in clinical nutrition, was the basis for his selection for the award.

The recipient of this year's Goldberger Award has not yet been chosen. However, it is hoped that the award will be presented at either the December, 1953, Clinical Meeting of the American Medical Association in St. Louis or at the San Francisco meeting in June, 1954.

OTHER COUNCIL ACTIVITIES

The Council's attention was called earlier this year to a group of infants with convulsions all of whom had been fed a liquid S.M.A. formula from birth or at a very early age. In most of the cases the convulsions appeared in infants under the age of six months. Cessation of convulsions tended to follow a change to standard milk formulas. All reported cases occurred after there had been a change in the fat composition of the product. The precise explanation of the difficulty has not been determined as of the date of the writing of this report. However, the product in question was voluntarily and completely removed from the market. It is regretable that this was not brought to the attention of the Council earlier, and it is hoped that physicians will report to the Council at once any suspicious or unusual reactions to any food product.

In cooperation with the Bureau of Health Education the Council office supplied source material and reviewed the script for a transcription on the history, development, and benefits of vitamin D milk. This was a part of a series of transcriptions entitled, "Yours for Health." The role of the Council in the early recognition and encouragement of the use of such a product is brought out. The almost complete eradication of rickets today is due in no small part to the widespread use of vitamin D milk. If present precautions were to be discontinued, rickets would again become prevalent within a very few months.

In the interest of developing sound eating habits in infants and children, the Council issued a statement declaring that prepared cereals intended for use in infant feeding would not be eligible for acceptance if they contained more than 5% added sugar. This statement will be published in THE JOURNAL in the near future. The Council is quite concerned about the increasingly greater use of sugar in foods prepared for infants and children and is watching the matter very closely.

COOPERATION

The Council office continues to answer hundreds of inquiries dealing with foods and nutrition from physicians, laymen, and various agencies and other organizations. The Council and the Council office has been requested to review many articles on nutrition written for popular consumption in order to check them for accuracy. Even though the Council is not able to do as much of this as it would like, it feels that every effort should be made to counteract the misrepresentations and half-truths about foods and nutrition appearing in some of the popular press. The prestige of the Council in this field and of the Association can do much to encourage the dissemination of truthful nutrition information.

The Council and the Food and Nutrition Board of the National Research Council have adopted a joint statement on the addition of specific nutrients to foods. This statement emphasizes the desirability of meeting the nutritional needs of the people by the use of natural foods as far as is practicable. However, it endorses the principle of adding specific nutrients to certain staple foods for the purpose of correcting deficiencies in the general diet and in maintaining good nutrition of the people as a whole. The following additions are recognized as being in the interest of the public health: enrichment of flour, bread, corn, and rice, and addition of vitamin D to milk, vitamin A to table fats, and iodine to table salt. No other fortifications or enrichments are considered to be necessary at the present time.

ORGANIZATION

The Council was saddened by the sudden death of its Chairman, Dr. Philip C. Jeans, on Oct. 22, 1952, while he was in Panama on an assignment for the World Health Organization. A tribute to him, expressing the sentiment of the entire Council was published in the March 14, 1953, issue of THE JOURNAL. Dr. Howard B. Lewis, who succeeded Dr. Jeans as Chairman, was unable to continue as an active member because of a serious illness necessitating his hospitalization for an indefinite length of time. Dr. James S. McLester, often called the dean of American medical nutritionists, tendered his resignation to the Council at its last meeting. It was regretfully accepted; however, he remains an active consultant of the Council. Dr. Grace A. Goldsmith of New Orleans was selected to complete Dr. Jeans' unexpired term on the Council. Two new members will be chosen shortly to fill vacancies created by illness and retirement. Dr. Charles Davidson of Boston is at present Chairman of the Council.

As usual, the services of the Council members were greatly in demand, both in this country and abroad. The Secretary attended a meeting of the National Food and Nutrition Institute in Washington, D. C., in December, 1952, and served as chairman of one of the three sessions. He also represented the Association on the Department of Agriculture's Food and Nutrition Advisory Committee, which serves as an advisory group to the department on research in the field of food and nutrition as related to the human welfare.

APPRECIATION

The Council wishes to express its appreciation for the cooperation and assistance of the Board of Trustees and the various departments at Association headquarters and to the many experts it has had occasion to consult during the past year.

Report of the Bureau of Investigation

The year that ended Aug. 31, 1953, was an interesting and busy one for the staff of the Bureau of Investigation. The primary function of the Bureau as an agency for the collection and dissemination of reliable information on quacks, cultists, faddists, "patent medicine" sellers, and others engaged in pseudomedicine has continued to be the answering of individual inquiries on individual subjects. No less important, however, were radio and television appearances, lectures before church and civic groups, and exhibits, which were all utilized as an effective means to spread the message of the Bureau in its fight against quackery.

This year there was widespread interest in an alleged injection treatment for cataract. Investigation into the background of the principal promoter and a considerable effort at cooperation with interested ophthalmologic groups made this single subject perhaps the most important one of the rather wide variety of subjects dealt with in the day-to-day business of the Bureau. That such cooperation resulted in a thorough exposure of the essential quackery engaged in by the principal was effectively brought out in a special report in THE JOURNAL by the Committee on Ophthalmology of the National Research Council on June 20, 1953. The principal promoter was, on last information, incarcerated in a state institution awaiting a hearing for alleged violation of the terms of his parole from a sentence involving the forging of narcotic prescriptions. In the category of "eye cures," more than 250 inquiries were received. Of these, the great majority were from physicians and patients wanting competent information on the fish lens protein treatment, because it appeared to be a most welcome relief from the prospect of major eye surgery.

The category that stands first in the volume of current inquiries, however, is that of cancer treatments. In the past year approximately 650 inquiries were received and handled on this subject alone. One of those persons who claim to have drug treatments for internal and external cancer suffered a major legal setback at the hands of a federal Circuit Court of Appeals at New Orleans. The court ruled that a trial judge had erred in permitting testimonial-givers to testify as to the nature of their disease and its alleged cure by a layman in Texas and ordered the judge to issue a decree of injunction in favor of the government under the Food, Drug and Cosmetic Act. The Koch treatment is, however, the major single item inquired about. This nostrum, which has been relabeled since the passage of the Durham-Humphrey Amendment to the Federal Food, Drug and Cosmetic Act in 1952, is still enjoying a considerable vogue among certain classes of people. It ("Glyoxylide") is now labeled as containing one part active ingredient to a trillion parts of distilled water. Only recently a federal court in Detroit upheld a cease and desist order issued by the Federal Trade Commission requiring William F. Koch, his brother, and his laboratory to cease advertising that their preparations have any therapeutic merit whatsoever. Nonetheless, the successor, an organization of ministers, continues to peddle the material, and another minister, a publisher and radio broadcaster, advertises this and other so-called cancer cures as regular features of his monthly magazine, "The Defender." A newcomer on the cancer scene, having a South American origin and a Chicago promotion, has had the benefit of considerable local newspaper publicity by reason of the inquiries of a legislative committee that held hearings in Chicago during the past spring.

Other subjects that had wide interest as far as inquiries go were the highly advertised reducing preparations and devices, and the advertising institutes, particularly those in western Missouri. Another advertiser, a Denver chiropractor, continued, by reason of his national advertising activities, to elicit inquiries from those less credulous. He recently invoked the technique, so popular recently, of having an alleged Congressional investigation by a solitary senator of a "plot" by the medical profession to keep disabled veterans from having the benefit of "free" chiropractic care.

Vitamin and mineral preparations continue to have widespread interest. In this field new products have appeared that are advertised to the lay public as a means whereby those who are underweight may become well-rounded and muscular. Of course, many such preparations are sold to the same public with slight variation to the effect that they are easy, drugless methods of losing weight!

Next in order of volume of inquiries were the devices sold for a variety of purposes. These include the mechanical massagers, the machines for diagnosing and treating disease as imitations of the "electronic reactions" of Abrams, and those that are sold for the purpose of erasing away excess fat. It may be of particular interest to note that there were only a dozen inquiries on "diabetes cures." Once this category was a major item in point of number of letters received. These, however, must be marketed in a rather circumspect manner because of the great risk of scrutiny by governmental regulatory agencies in the "patent medicine" field.

The Bureau, in cooperation with the Bureau of Exhibits, showed the Mechanical Quackery exhibit at the annual meeting of the Medical Society of Virginia at Richmond and at the Federation of Women's Clubs in Washington, D. C. Valuable assistance was rendered here by the personnel of the Public Relations Department. This exhibit was also shown at the annual meeting of the Student A. M. A. in Chicago. A new exhibit entitled "Fooling the Fat," which contrasts advertising claims for reducing pills, powders, and "plans" with the item actually purchased, was shown at the Clinical Meeting in Denver, at the Chicago Dental Society Midwinter Meeting, and at the Summer Conference of Indiana Farm Women at Purdue University, Lafayette, Ind.

The Director participated in radio programs in Denver and in Lafayette, Ind. Television programs were participated in at Chicago and Minneapolis, the latter under the auspices of the Minnesota State Medical Association. The director also gave talks before several organizations, including the Summer Conference of Farm Women at Purdue, Ind., the Annual Short Course on School and Community Health at Indiana University, the Stritch Chapter of the Student A. M. A. at Stritch School of Medicine, Chicago, the Hennepin County Medical Society at Minneapolis, the Woman's Auxiliary of the American Society of Clinical Pathologists, and the Council and House of Delegates of the Arkansas Medical Society at Little Rock. Talks were also given before service clubs, church organizations, and high school classes.

The Bureau exchanges information with government agencies, better business bureaus, radio and television broadcasting firms, newspapers, and magazine writers. It also serves as a clearinghouse of information for state and local medical societies, state medical boards, and health departments. The Bureau maintains files on and publishes occasional reports on medical impostors in THE JOURNAL.

Conclusion

The board will submit a supplementary report at the opening session of the House of Delegates covering a few items on which complete information is not as yet available.

Respectfully submitted,

DWIGHT H. MURRAY, *Chairman.*
GUNNAR GUNDERSEN, *Vice Chairman.*
EDWIN S. HAMILTON, *Secretary.*

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

To the Members of the House of Delegates of the American Medical Association:

This report covers the period from Oct. 1, 1952, to Sept. 30, 1953.

The major concerns of the Council on Medical Education and Hospitals during the past year have been with matters referred to it by the House of Delegates, postgraduate medical education, foreign medical schools, the first World Conference on Medical Education, the survey of medical education, and the financial needs of the medical schools.

The Council has continued the many programs it conducts that are aimed at contributing to and stimulating the improvement of medical education at all levels. These programs include the accrediting of educational programs in nine major fields, the compilation and dissemination of information and statistics concerning medical education and related activities, and conferring, consulting, and collaborating with a large group of agencies, institutions, and organizations that have an interest in medical education.

Matters Referred to the Council by the House of Delegates

At its December, 1952, meeting, the House of Delegates requested the Council to define the distinction between graduate and postgraduate education. In response to this request the Council has prepared the following definitions:

Graduate Medical Education consists of those programs pursued by persons possessing the degree of Doctor of Medicine which are primarily designed to *prepare them for entrance into a specific field of medicine.* Such programs include all specialty training as well as academic work in the clinical and basic medical sciences and may lead to board certification or an advanced academic degree. Graduate programs are usually conducted on a full-time basis over a period of from one to several academic years. They are generally of a formal nature as residencies, fellowships, preceptorships, or intramural academic work and are generally conducted by medical schools, hospitals, or graduate medical schools.

Postgraduate Medical Education consists of those educational activities engaged in by persons possessing the degree of Doctor of Medicine which are primarily designed to *keep them abreast of their own particular field in medicine.* Such activities are intended both to refresh the person in various aspects of his medical education and inform him of the new developments within his field and do not lead to any formal advanced standing in the profession. Postgraduate programs may be on a full-time or part-time basis but are usually of relatively short duration, i. e., days to months. The organization of these programs may be formal or informal, more often the latter. They are conducted in a great variety of forms using many methods and techniques. They are sponsored by a diverse group of institutions, schools, and organizations. Postgraduate programs may also include special training in very narrow fields of medicine, such as subspecialties and new areas of study, as well as short basic science courses.

At the June, 1952, meeting, the House of Delegates instructed the Council to undertake an immediate restudy and reevaluation of the policy of establishing residencies and internships for the purpose of correcting the gross imbalance between the large number of established residencies and internships and the small number of physicians available to fill them. At the same meeting the House of Delegates requested the Council to give careful study and consideration as to what rearrangements, if any, can be made in the length of certain residency programs in the interest of public welfare. At the December, 1952, meeting, the House of Delegates referred to the Council a resolution from the Section on General Practice requesting that until the residency training program in general practice has been properly augmented there be fewer approvals of specialty residency programs in any hospitals except those fully associated with medical schools.

Since all of these resolutions bore directly on the Council's activities in the field of approving hospitals for internship and residency training, the Council appointed a special subcommittee to review carefully the current policies of the Council with respect to standards for approved programs and the Council's practices with respect to the evaluation of individual hospitals seeking approval for internship and residency training. The following sections of the report of the subcommittee, which are particularly pertinent to the resolutions referred to above, may be quoted:

It was the consensus of the committee that a restudy and re-evaluation of the policies relating to internships had been accomplished through the completion of the study made by the Advisory Committee on Internships and the adoption of the revised Essentials of an Approved Internship.

It was the consensus of the committee that the restudy and re-evaluation of policies relating to residency training were being and would be constantly evaluated by the conference committees and residency review committees which had been and are being established in collaboration with the Boards and Colleges.

The committee was of the opinion that the length and content of approved training programs in a specialty are being recurringly evaluated by the appropriate conference committee or residency review committee and further that the classifying of approved services in terms of number of years is necessary in order to provide accurate information for the resident in planning his training program.

The establishment of general practice residencies during the past two to three years, from the committee's point of view, provides adequate opportunity for graduates seeking advanced training before going into general practice. It was noted that last year approximately 40 per cent of these residencies were filled. There would not appear, therefore, to be any immediate need for the establishment of additional residencies of this type. It was recognized that many graduates intending to enter general practice take residency training in internal medicine, obstetrics-gynecology, pediatrics or surgery after completing their internship. The number of residents in general practice residencies, therefore, is not an accurate indication of the number of graduates planning to become family physicians. While the committee was of the opinion that the development of well organized programs preparing a graduate for general practice should be encouraged, it did not believe that the number of residencies in the specialties could be restricted on this basis.

The subcommittee was asked by the Council to determine whether any special studies over and above those now being carried out should be instituted. The committee was of the opinion that through the activities of the conference and review committees which have been established by the Council in the various specialties in which residency training is offered, the major problems relating to residency training were being subjected to continuous scrutiny. After reviewing the subcommittee's report, the Council was agreed that it would not be advisable to initiate any additional studies of residency training at this time since an effective mechanism now exists for resolving such general and special problems related to residency training as may be referred to the Council.

At the June, 1953, meeting the House of Delegates voted to abolish the rule (in the revised Essentials of an Approved Internship approved by the House of Delegates in December, 1952) whereby approval may be withdrawn from an internship program which for two consecutive years fails to obtain at least two-thirds of its stated complement of interns. The Council has taken appropriate note of this action of the House of Delegates.

At the June, 1953, meeting, the House of Delegates also voted that a further study of the internship be continued by a committee appointed by the Speaker of the House of Delegates, at least half of the members of which were to be doctors in private practice not connected with medical schools or affiliated hospitals. The Council will be pleased to be of assistance to this committee in any way that it can.

At the June, 1953, meeting, the House of Delegates approved a resolution condemning the interference of teaching institutions with the operation of the National Intern Matching Plan and asked for a restudy of the problem so that a more equitable allocation of interns may be achieved. The American Medical Association's representatives to the corporation known as the National Intern Matching Program, Inc., were instructed to request that corporation to restudy the problem and implement its improvement. This action of the House of Delegates will be transmitted to the Directors of the National Intern Matching Program at their next meeting with a request that appropriate action be taken.

National Commission on Accrediting

For the past several years the National Commission on Accrediting, an organization formed by seven major associations of colleges and universities, has been making a study of the activities of accrediting agencies. This commission was formed because of the concern of colleges and universities over the multiplicity of accrediting agencies whose standards they had to meet and because of the concern of colleges and universities that they were surrendering control of their educational programs and policies to the accrediting agencies. The commission at one time gave consideration to a proposal that the accrediting activities of all professional agencies such as the Council on Medical Education and Hospitals be abolished and that the accrediting of institutions of higher learning should be the responsibility of the six major regional accrediting associations in the United States.

For many reasons which are beyond the scope of this report to review, the Council on Medical Education and Hospitals believed that this would be a backward step as far as medical education was concerned. The Council vigorously presented its point of view through correspondence and in conference with representatives of the National Commission on Accrediting during the past year. It is with satisfaction that we report that while the National Commission on Accrediting has recommended to its member universities and colleges that they no longer deal with professional accrediting agencies in many fields, they have formally recognized that the Council on Medical Education and Hospitals and its collaborator, the Association of American Medical Colleges, are the agencies best fitted to establish standards and accredit programs in the field of medicine.

The National Commission on Accrediting has suggested that the Council and the Association of American Medical Colleges give serious consideration to coordinating their activities as far as possible with those of the regional accrediting associations. The Council and the Association of American Medical Colleges have made it clear that they intend to maintain their current independent programs but that they will be glad to explore fully the possibility of coordinating visits to medical schools as far as is practical with visits to their parent universities by the regional accrediting associations.

At the moment plans are being made for a pilot endeavor of this type with the Middle States Association of Colleges and Secondary Schools. This experiment will be studied very carefully to determine just how far it is desirable for the Council and the Association of American Medical Colleges to proceed in this direction.

First World Conference on Medical Education

Five members of the Council and its staff attended and took an active part in the first World Conference on Medical Education held in London under the auspices of the World Medical Association during the last week of August, 1953. The conference was acclaimed as an outstanding success by all who attended it. It is hoped that similar opportunities for stimulating exchanges of views and experiences by medical educators and physicians from all parts of the world can be arranged at appropriate intervals. The World Medical Association is deserving of the highest commendation for undertaking this important program which should lead to improving medical education throughout the world.

Foreign Medical Schools

The problem of evaluating the education and preparation of physicians who attended foreign medical schools remains an important one for licensing boards, hospitals, and other groups and organizations in the United States. The preliminary list of foreign medical schools issued in 1950 by the Council, which has subsequently been revised three times, is proving to be of increasing value.

Several groups and individuals have proposed on a number of occasions in recent years that the Council should expand its staffs so as to be in a position to make detailed surveys of medical schools in other countries comparable to the surveys regularly made of American and Canadian medical schools. While the Council has this matter under serious consideration, the situation is obviously such a complex and involved one that the Council is not prepared at this time to determine how far it should develop this program.

Following the World Conference on Medical Education in London, three representatives of the Council at the invitation of the schools concerned made a detailed visit to the medical schools of one European country. At the time this report is being written, it is too early to predict whether this experience will give indication as to the desirability or feasibility of the Council's attempting to make direct investigations of other foreign medical schools.

The Council has just completed a new booklet of information for the guidance of foreign-trained physicians coming to the United States and of Americans who are considering studying medicine abroad. This booklet, which brings together basic facts and information, should be helpful to the two groups mentioned in evaluating their status and opportunities for medical practice in the United States.

Survey of Medical Education

The final report of the Survey of Medical Education sponsored by the Council and the Association of American Medical Colleges appeared in book form during the summer of 1953. The report is entitled "Medical Schools in the United States at Mid-Century" and was prepared by Dr. John E. Deitrick, director of the survey, and Dr. Robert C. Berson, associate director. It is published by McGraw-Hill Book Co., New York. All physicians interested in medical education are urged to read the report. A comprehensive review of the report appeared in the 1953 Educational Number of THE JOURNAL, Sept. 12, 1953.

Financial Needs of Medical Schools

During the past year the Council has continued to collaborate closely with the American Medical Education Foundation and the National Fund for Medical Education in their efforts to secure additional financial support for the medical schools. As this report is being written, the Council and the Association of American Medical Colleges are initiating a joint study of the current needs of the medical schools. This study, which will be completed late in 1953 or early in 1954, should provide valuable, up-to-date information on which to base accurate estimates of the over-all needs of the medical schools. It is believed that this information will be of material assistance to the American Medical Education Foundation and the National Fund in presenting the needs of the medical schools to the medical profession, business, industry, and the public generally.

Postgraduate Medical Education

During the past year a member of the Council's staff has completed an intensive nationwide study of the activities of medical societies, medical schools, hospitals, health departments, and other organizations in the field of postgraduate medical education for the purpose of determining the major trends and problems in this field. A detailed report of this study is now being completed and should be ready for publication early in 1954.

The Council intends to study this report carefully to determine the type of future program it should sponsor for the stimulation and improvement of postgraduate education. Postgraduate education is assuming a position of increasing importance to the medical profession, and the Council believes that, as a result of the study just completed, it will be in a better position to assist in the further development of postgraduate medical education than it has been previously.

Division of Hospitals and Graduate Education

In August of this year a Division of Hospitals and Graduate Education was established as a section of the Council's staff. The director of this division, Dr. Edward H. Leveroos, is responsible for the administration of the Council's internship and residency approval programs and its activities in the field of hospital accreditation. Approval by the Board of Trustees of the establishment of this division is evidence of the increasing importance which graduate education has assumed in present day medical education and of the Council's interest in maintaining a position of leadership in this field.

The responsibilities of the division include consultations, both direct and through correspondence with members of hospital staffs and administrators initiating or conducting internship or residency programs, evaluation of applications for approval of these programs, organization of the Council's field inspection service, liaison with the individual American Boards in the medical specialties as well as with the Advisory Board for Medical Specialties, participation in the organization and conduct of the program for internship appointments as sponsored by the National Internship Matching Plan, Inc., liaison with the offices of the Surgeons General of the medical departments of the federal services, development of standards for approval of graduate training programs, and the compilation of data for publication in the Annual Report and the Directory of Approved Internships and Residencies. Within the past year there has been an increasing volume of correspondence from graduates of foreign medical schools seeking internship and residency appointments to hospitals in this country. Every effort has been made to assist these physicians to obtain positions in hospitals desiring their services.

During the past year the field staff of the Council was increased to nine full-time physicians, each of whom has responsibility for the inspection of hospitals in an assigned territory. Approximately 50% of the time of these staff representatives is spent in conducting surveys for the Joint Commission on Accreditation of Hospitals, the rest being devoted to an evaluation of internship and residency programs. Dr. Arthur Springall, who served for a time as a member of the field staff, has recently been made responsible for the supervision of the Council's internship approval program under the direction of Dr. Leveroos.

A summary of the activities of the field staff in visiting hospitals throughout the country during the past year is presented in tabular form in this report. Under present arrangements with the Joint Commission, the Council's representatives conduct the survey work for accreditation of those hospitals approved by the Council for internship or residency training. On completion of this basic survey, the internship and residency programs for which the hospital is approved are reviewed and evaluated. For the reporting period, 677 hospitals were visited, with 350 internship programs and 1,702 residency programs examined. In addition, since Jan. 1, 1953, 290 surveys for accreditation were made in behalf of the Joint Commission. Each member of the field staff has from 150 to 160 hospitals for which he is responsible. The inspection program is set up on a two year basis so that each field representative will visit from 75 to 80 hospitals annually. The staff has been untiring in its efforts to complete assignments on schedule, year after year. Without the basic contributions which these physicians make to the Council's program, it would be impossible to carry it out successfully.

One of the special issues of The Journal is the Internship and Residency Number, in which the Council's Annual Report on graduate education and lists of approved services is published. This year, the report indicated that there were 1,313 hospitals in the United States and its possessions approved for internship or residency, or both. In these hospitals, there was a total of 7,645 interns and 16,867 residents on duty as of Sept. 1, 1952. Included in the total number of interns assigned, were an estimated 1,300 to 1,400 graduates of foreign medical schools. According to the report, 72% of internships were filled last year. This was the same percentage of positions occupied as for the year previous. The number of internships vacant has also remained relatively constant for the past two years, with about 3,000 positions reported unfilled. The residency occupancy rate for the years 1951-1952 and 1952-1953 remained at 76%, although the number of residents actually assigned increased from 15,851 reported a year ago to 16,867 this year. The Council points out in the report that the problem of house staff shortages now involves interns and residents to almost the same extent and that any consideration of the problem should be in terms of both internships and residencies rather than viewing the intern shortage or residency shortage as separate situations.

Another publication for which the Division of Hospitals and Graduate Education is responsible is the Residency Information Bulletin, published quarterly. The bulletin gives current information on available residency appointments in Council-approved hospitals. Prior to publication, all hospitals are circularized relative to residency vacancies. This information is forwarded without charge to any physician interested in applying for an appointment. The bulletin is also distributed to approximately 250 military posts, camps, and stations, where it is made available to medical officers about to be released from service who may be interested in residency training. Approximately 1,500 copies of each issue are furnished on request as a service to physicians, hospitals, medical schools, and a number of federal and nonfederal organizations.

During the past year, the Council has worked closely with 18 of the 19 existing American boards in the approval of residency programs. In the single specialty not represented, ophthalmology, the American Board of Ophthalmology accepts training in any Council-approved hospital but does not wish to participate in the evaluation of residency programs. The Council is currently engaged in discussions with a number of the boards to the end of developing a more direct collaboration between the Council and these boards. It is anticipated that by Jan. 1, 1954, joint committees will be established with representatives from both organizations in at least nine specialties. These committees will evaluate residency programs in the specialty concerned and will act in an advisory capacity in the development of training standards. Joint committees of this type have been in operation for a number of years in internal medicine (Residency Review Committee in Medicine), and in general surgery (Conference Committee on Graduate Training in Surgery). In these two specialties, the "American Colleges" are represented on the committee as well as the Council and the Board, i. e., the American College of Physicians on the former committee, and the American College of Surgeons on the latter. All administrative work relating to the activities of these committees as well as the actual inspection of hospitals is carried out through the Division of Hospitals and Graduate Education of the Council. The Council wishes to express its sincere appreciation for the valued cooperation of the boards and colleges in this work. Without the combined efforts of all of these organizations, the present approval program for graduate education could not be so effectively conducted.

In the Council's report last year, mention was made of the fact that representatives of the American Board of Anesthesiology had met with the Council in an attempt to resolve certain problems which had arisen relative to the approval of residency programs in this specialty. Conferences with representatives from this board have continued during the past year.

Advisory Committee on Internships

In its report to the House of Delegates last year, the Council noted that the Advisory Committee on Internships would complete its 15 month investigation and study of the internship prior to the first of the year. The Report of the Advisory Committee, summarizing its views on the form and content of the internship and the manner in which it should be conducted, was referred to the House at the Denver meeting along with the revised Essentials of an Approved Internship, which were adopted at that meeting, with an amendment to the latter approved by the House in June. Both the report and the essentials were published in The Journal and copies distributed to all hospitals approved for intern training. That these two documents will serve as a frame of reference for any future evaluation of the internship is evident. In its report, the committee stressed the fact that the internship is undergoing major changes and urged that the Council "continue its policy of holding the place of the internship (in present-day medical education) under close scrutiny." The Council considers the report in general, and this recommendation in particular, as eminently sound and wishes to commend the committee for the important contribution it has made to medical education.

National Intern Matching Plan

The Matching Plan, first introduced in 1950, will again be the official method for appointing interns for the coming year. The Council has actively supported this plan since its inception through representation on the operating committee and on the executive committee of the corporation. Other organizations sponsoring the plan include the American Hospital Association, the Catholic Hospital Association, the Protestant Hospital Association, the Association of American Medical Colleges, with liaison members from the medical departments of the federal services. This year for the first time, there is direct student representation on the operating committee with one member from the Student American Medical Association and one member at large. The Matching Plan completed its second successful year of operation last year with 843 hospitals and 6,033 students participating. Over 80% of the applicants received appointments to hospitals first in their preference lists; an additional 10% were appointed to their second choice hospitals, with the remaining 10% placed in hospitals the applicant had rated third or lower, or not matched.

There is apparently still some misunderstanding as to the purpose of the plan. It does not purport to "distribute" interns.

A hospital participating in the plan may or may not obtain its requested number of interns, depending on the number of applicants who signify their desire to accept appointment at that hospital and who are not matched with another hospital higher in their preference rating. The primary purpose of the plan is to give effect to the student's expressed choice of the hospital at which he desires to intern and the hospital's preference of persons applying to it. The plan in no way interferes with the student's free selection of the hospital of his choice. It does have the effect of relieving undue pressure on the student in making that choice. Neither does the plan interfere with proper negotiations between hospital and applicant. It assures the hospital of the appointment of those interns who have applied to it and who have given the hospital high enough preference in their confidential list. The Council is of the opinion that the Matching Plan as presently conducted affords the best available method for the appointment of interns in an orderly and equitable manner and as such warrants the support of the medical staffs of all hospitals in which intern training is being conducted.

Joint Commission on Accreditation of Hospitals

As pointed out, the Council staff has been conducting surveys for the Joint Commission since Jan. 1, 1953. In general, the field staff of the Council visits those hospitals approved for intern or residency training, conducting a combined survey of the hospital from the standpoint of the Joint Commission's program and the Council's approval for intern or residency training. It should be noted that accreditation by the Joint Commission, while a prerequisite for approval by the Council, does not involve evaluation of the hospital from the standpoint of its educational program. This function is the responsibility of the Council on Medical Education and Hospitals collaborating, in the case of residencies, with the American boards and the American College of Physicians and the American College of Surgeons. Participation in the Joint Commission's program has enabled the Council's representative to obtain a comprehensive view of the hospital which is of distinct value in considering its teaching potential. An excellent rapport has been developed between the offices of the Joint Commission and the Division of Hospitals and Graduate Education, which has been most helpful in resolving problems in which the Council and the commission have been interested. The Council has appreciated the assistance and support it has received from this organization and looks forward to a continuance of the friendly cooperation which has existed since the Commission was activated.

Approved Examining Boards

There have been no new examining boards approved since 1951. By action of the Council and the Advisory Board for Medical Specialties at their meetings in February, 1953, however, the American Board of Preventive Medicine was authorized to certify candidates in two fields, public health, as had been done since establishment of the board, and aviation medicine. Training standards in the latter subspecialty are currently being developed. As yet, there have been no candidates certified in aviation medicine. It is anticipated, however, that a founder member group will have been established in the near future. At present, there are 19 examining boards approved by the Council and the Advisory Board for Medical Specialties, including 11 in the surgical specialties, 6 in the medical specialties, and 2 in the clinical-laboratory field.

Activities of the Section on Hospital Service and Technical Schools

The Section on Hospital Service and Technical Schools of the Division of Hospitals and Graduate Education deals with the registration of hospitals and the approval of schools for medical technologists, x-ray technicians, occupational therapists, physical therapists, medical record librarians, and medical record technicians. These activities are carried out in accordance with standards adopted by the House of Delegates and involve the cooperation of county medical societies in the evaluation of hospital applications and the assistance of national technical associations in the study and organization of training programs relating to technical personnel. Other functions include the collection and compilation of statistical data, the preparation of lists of acceptable hospitals and technical schools, and the publication of an annual report on Hospital Service in the United States. From Oct. 1, 1952, to Sept. 30, 1953, the number of hospitals registered by the American Medical Association increased from 6,717 to 6,769. In this period 288 new registrations took place whereas 236 hospitals were closed or transferred to the unclassified file. The respective county medical societies, as well as district councilors, gave valuable assistance in the evaluation of hospital applications and in many instances submitted their recommendations on the basis of personal visits of inspection. In addition, 30 hospitals were inspected for registration by members of the Council's staff. The 1952 hospital report published in THE JOURNAL, May 9, 1953, listed 6,665 registered hospitals with a total of 1,541,615 beds and 93,749 bassinets.

In the technical fields the Council lists 551 approved schools in medical technology, 328 for x-ray technicians, 37 schools of physical therapy, 27 schools of occupational therapy, and 24 schools for medical record librarians. This represents in the last year a net gain of 46 schools in medical technology, 13 in x-ray technique, 6 in physical therapy, and 2 in the area of medical record library science. In this connection, it should be noted that when the Council's standardization program began in 1936 the approved schools of medical technology totaled 96, the training programs in physical therapy 13, and the occupational therapy schools 5. Similarly, in 1943 the acceptable courses for medical record librarians numbered only 10, while in 1945 the initial list of x-ray schools represented a total of 112. There has likewise been a general increase in technical personnel from year to year, with the schools of medical technology listing 2,063 graduates in 1952, the x-ray programs 1,156, physical therapy 582, occupational therapy 441, and the medical record schools 92. It is evident, however, that the present production rate is not sufficient to meet existing demands, as critical shortages are still continuing in many areas. This need is receiving full consideration by the Council and the respective professional and technical organizations, and every effort is being made to stimulate recruitment and the establishment of additional schools, particularly in areas where training facilities have not yet been fully developed.

Recognizing that the present one year training program for medical record librarians, based on two years of college or graduation from an accredited school of nursing, cannot alone supply the required personnel in this field, the American Association of Medical Record Librarians has requested that a supplemental nine months' course be established for high school graduates. Standards for this type of training, presented to the House of Delegates last June under the title "Essentials for the Training of Medical Record Librarians," were given temporary approval with the understanding that they be resubmitted to the House for further consideration and final action at the December, 1953, session. These "Essentials" were printed in THE JOURNAL, June 27, 1953, page 830. Final approval by the House is formally requested at this time. Interest in this program is developing rapidly as many institutions are seeking additional information and fifteen have already requested application forms.

The needs in medical technology are now being investigated by a study committee of the American Society of Clinical Pathologists, whose Board of Schools of Medical Technology has, in the last year, completed a survey of the approved laboratory schools. The board is continuing to assist the Council in the evaluation of new applications and has cooperated in the revision of the "Essentials of an Acceptable School of Medical Technology," appended to this report and submitted for final approval by the House. Changes in the training requirements in physical therapy are likewise under consideration, and the Council is also continuing to evaluate the educational programs in occupational therapy. Surveys of the approved schools of x-ray technique have previously been completed with the full cooperation of the American College of Radiology.

Acknowledgment is also made at this time of the excellent cooperation received from the Council on Physical Medicine and Rehabilitation, the American Occupational Therapy Association, the American Physical Therapy Association, and the American Association of Medical Record Librarians.

Annual Congress on Medical Education and Licensure

The 49th Annual Congress on Medical Education and Licensure, sponsored by the Council on Medical Education and Hospitals and the Federation of State Licensing Boards, was held in Chicago Feb. 8 to 10, 1953. The attendance was the largest ever recorded and numbered over 550. Featured on the program were panel discussions of the new experimental program of medical education at Western Reserve and the Report of the Council's Advisory Committee on Internships. Many other interesting and timely topics were presented in the form of papers and discussions. The next Congress will be held Feb. 7 to 9, 1954, in Chicago, and all physicians interested in medical education are invited to attend.

Collaboration with Other Agencies

The Council has continued to collaborate as it has from the beginning of its work with other organizations and agencies that have active interests in one or more phases of medical education. Because of the importance of maintaining close cooperation among these various groups, efforts to promote collaboration have become one of the most significant parts of the Council's program in terms of time, energy, and importance. As in previous years, the close relations that the Council enjoys through regularly constituted liaison committees with the Association of American Medical Colleges and the Advisory Board for Medical Specialties have been particularly beneficial. Of increasing importance are the recently established conference committees on graduate training with the American College of Surgeons and the American College of Physicians.

Conjoint activities with these and other organizations have been varied in nature and have involved members of the Council, the Secretary, the Director of the Division of Hospitals and Graduate Education, and other members of the staff. These cooperative enterprises have included consultations, participation in conferences, meetings, and the work of advisory committees in joint sessions and studies. A partial list of the agencies and organizations with which the Council has collaborated during the year include:

Advisory Board for Medical Specialties
Alpha Omega Alpha Honorary Fraternity
American Academy of General Practice
American Association of Medical Record Librarians
American College of Physicians
American College of Radiology
American College of Surgeons
American Congress of Physical Medicine
American Dental Association
American Hospital Association
American Medical Education Foundation
American Nurses Association
American Occupational Therapy Association
American Pharmaceutical Association
American Physical Therapy Association
American Public Health Association
American Registry of Physical Therapists
American Registry of X-Ray Technicians
American Society of Clinical Pathologists
American Society of X-Ray Technicians
American Veterinary Medical Association
Association of American Medical Clinics
Association of American Medical Colleges
Association of Canadian Medical Colleges
Board of Registry of Medical Technologists
Boards of Schools of Medical Technology
Canadian Medical Association
Catholic Hospital Association
College of American Pathologists
County Medical Societies
Federal Civil Defense Administration
Federation of State Medical Boards of the United States
Health Resources Advisory Committee, Office of Defense Mobilization
House of Representatives Armed Services Committee
Institute of Inter-American Affairs
Institute of International Education
Joint Committee on Medical Education in Time of National Emergency
National Board of Medical Examiners
National Fund for Medical Education
National Internship Matching Program, Inc.
National Committee for Resettlement of Foreign Physicians
Office of Defense
Pan American Sanitary Bureau
Public Health Service
Selective Service System
Senate Armed Service Committee
Southern Regional Education Board
State Department
State Licensing Boards
State Medical Associations
Student American Medical Association
Survey of Medical Education
United States Air Force
United States Army
United States Navy
United States Office of Education
Veterans Administration
Western Regional Education Board
World Medical Association

Medical Schools Visited

During the year Oct. 1, 1952, to Sept. 30, 1953, the following medical schools were visited for consultations, inspection or other purposes: University of British Columbia School of Medicine, University of Colorado School of Medicine, University of Washington School of Medicine, University of Oregon School of Medicine, University of Utah School of Medicine, Stritch School of Medicine, Wayne University College of Medicine, University of Miami School of Medicine, University of Puerto Rico School of Medicine, Medical College of Alabama, Chicago Medical School, New York Medical College, Flower and Fifth Avenue Hospitals, State University of New York College of Medicine at New York City, Medical College of Virginia, University of Ottawa Faculty of Medicine, University of Saskatchewan Faculty of Medicine, and the University of Western Ontario Faculty of Medicine.

Inspection of Hospitals and Technical Schools

Inspection of hospitals and technical schools made by the Council during the year Oct. 1, 1952, to Sept. 30, 1953, are summarized as follows:

Registration	30
Accreditation (Joint Commission)	290
Intern training	74
Residency training	282
Intern and residency training	276
Technical schools	15
Total	967
Intern programs reviewed	312
Residency training programs reviewed	1,702
Total	2,014

Summary of Hospitals and Technical Schools

Figures for approved hospitals and technical schools with changes occurring during the year Oct. 1, 1952, to Sept. 30, 1953, are as follows:

Registration of Hospitals	
Hospitals registered, Oct. 1, 1952	6,717
New institutions registered to Sept. 30, 1953	288
Closed or transferred to unclassified file	236
Hospitals registered Sept. 30, 1953	6,769
Internship Approval	
Hospitals approved for intern training, Oct. 1, 1952	872
Approved to Sept. 30, 1953	14
Removed from approved list	23
Hospitals approved for intern training, Sept. 30, 1953	863
Residency Approval	
Hospitals approved for residency training, Oct. 1, 1952	1,161
Approved to September 30, 1953	33
Removed from approved list	18
Hospitals approved for residency training Sept. 30, 1953	1,176
Residency Training Programs	
Programs approved for residency training, Oct. 1, 1952	4,656
Approved to Sept. 30, 1953	196
Removed from approved list	100
Programs approved for residency training, Oct. 1, 1953	4,752
Medical Technology Schools	
Approved schools, Oct. 1, 1952	505
Approved during year	57
Removed from approved list	11
Approved schools, Sept. 30, 1953	551
Medical Record Librarian Schools	
Approved schools, Oct. 1, 1952	22
Approved during year	2
Removed from approved list	0
Approved schools, Sept. 30, 1953	24
Occupational Therapy Schools	
Approved schools, Oct. 1, 1952	27
Approved during year	0
Removed during year	0
Approved schools, Sept. 30, 1953	27

Physical Therapy Schools	
Approved schools, Oct. 1, 1952	31
Approved during year	6
Removed from approved list	0
Approved schools, Sept. 30, 1953	37
X-Ray Schools	
Approved schools, Oct. 1, 1952	315
Approved during year	17
Removed from approved list	4
Approved schools, Sept. 30, 1953	328

Council Publications

During the period Oct. 1, 1952, to Sept. 30, 1953, the Council was responsible for preparing material for six numbers of THE JOURNAL:

Postgraduate and Continuation Courses for Physicians	Dec. 13
Hospital Service in the United States	May 9
Medical Licensure Statistics	May 30
Postgraduate and Continuation Courses for Physicians	June 12
Medical Education in the United States	Sept. 12
Internship and Residency Number	Sept. 26

Other regular publications of the Council included:

Proceedings of the 1953 Annual Congress on Medical Education and Licensure
Choice of a Medical School. (Prepared for the guidance of prospective medical students)
Approved Colleges of Arts and Sciences
Foreign Medical Schools
Reciprocity and Endorsement Policies in Medical Licensure
Status of Requirements for Medical Licensure for Foreign Trained Physicians
Federation Bulletin (a monthly bulletin established by and published for the Federation of State Medical Boards of the United States)
Residency Information Service (a list of current vacancies in residency positions)
Schools for Medical Technologists
Schools for Physical Therapists
Schools for Occupational Therapists
Schools for Medical Record Librarians
Schools for X-Ray Technicians

The Council also has reprinted for distribution a number of articles dealing with questions relating to the Council's work and responsibilities including a weekly listing in THE JOURNAL of coming examination and reciprocity meetings of state licensing boards, basic science boards, and examining boards in the medical specialties. In addition, the Council has published numerous statements in THE JOURNAL from time to time concerning current actions of the Council.

Changes in Headquarters Staff

The Council is happy to announce the appointment of Dr. Edward L. Turner, Dean of the University of Washington School of Medicine since 1946, as Secretary of the Council to succeed Dr. Donald G. Anderson, who resigned the Secretaryship on Oct. 1, 1953, to become dean of the University of Rochester School of Medicine and Dentistry.

The Council regrets the resignation of Dr. Francis R. Manlove, who has been Associate Secretary of the Council since 1950. Dr. Manlove resigned to accept appointment as director of the Medical Center and dean of the department of medicine at the University of Colorado. Dr. Manlove has been a valued member of the Council's staff, and he has the best wishes of the Council in his important new work.

Memorial to Dr. Reginald Fitz and Dr. Frank H. Lahey

The Council was grieved during the past year by the deaths of two former distinguished members, Drs. Reginald Fitz and Frank H. Lahey. Dr. Fitz, who demonstrated his great capacities for leadership in many fields of medical education, served as an active member of the Council for 21 years beginning in 1928. He will long be remembered for the kindly wisdom that he brought to the deliberations of the Council and for his untiring and energetic participation in the work of many of the Council's most important subcommittees. Dr. Lahey, one of the great leaders of American medicine of modern times, served as a member of the Council from 1938 to 1940. When Dr. Lahey left the Council to assume the office of President-Elect of the American Medical Association, he continued to demonstrate his interest in medical education and the problems of the Council. As evidence of this, during the months immediately preceding his death, Dr. Lahey had made many special trips to a number of cities throughout the nation to speak on behalf of the important work of the National Fund for Medical Education, of which he was one of the original trustees. Medical education has lost two splendid friends and vigorous workers in the passing of these great leaders.

Appreciation

It is a pleasure for the Council to express its appreciation for the fine cooperation it has received from many organizations, institutions, and individuals in carrying out its various programs. The Council wishes to make special mention of the support and encouragement it traditionally receives from the officers, Board of Trustees, and members of the House of Delegates of the American Medical Association. Without this support and encouragement, the Council could make little progress in its effort to discharge the responsibilities that it carries on behalf of American medicine in the important field of medical education and hospital affairs.

This report was prepared by Dr. Donald G. Anderson.

Respectfully submitted,

H. G. WEISKOTTEN, Chairman.
GUY A. CALDWELL.
JOHN W. CLINE.
JAMES M. FAULKNER.
VICTOR JOHNSON.
LELAND S. MCKITTRICK.
FRANKLIN D. MURPHY.
W. L. PRESSLY.
CHARLES T. STONE.
HARVEY B. STONE.
EDWARD L. TURNER, Secretary.

APPENDIX

Essentials of an Acceptable School of Medical Technology, Revised to December, 1953

PREAMBLE

Two organizations are primarily concerned with the training of medical technologists, the Council on Medical Education and Hospitals of the American Medical Association and the American Society of Clinical Pathologists. Two Boards of the American Society of Clinical Pathologists represent this Society. The Board of Schools of Medical Technology is primarily concerned with the evaluation and inspection of schools of medical technology, acting in an advisory capacity to the Council, assisting also in the maintenance of high standards of education and in the development of new schools of medical technology. The Board of Registry of Medical Technologists investigates and certifies the competency of the technologists.

The Council, with the cooperation of the Board of Schools of Medical Technology and the Board of Registry of Medical Technologists, has established the following standards for this type of training for the information of schools, physicians, hospitals, prospective students, and others and for the protection of the public.

Technologists are being trained in these schools to work under the direction of qualified physicians and not as independent practitioners.

I. ADMINISTRATION

1. Acceptable schools for training medical technologists may be conducted by approved medical schools, hospitals, or other acceptable laboratories suitably organized in accordance with present educational standards.

2. All training of technologists shall be under competent medical control.

3. Resources for continued operation of the school should be insured through regular budgets, gifts, or endowment, but not entirely through students' fees. Experience has shown that commercial schools operated for profit frequently do not adhere to proper ethical and educational standards and therefore are not acceptable.

II. ORGANIZATION

4. Adequate space, light, and modern equipment should be provided in the laboratory department. A library containing up-to-date references, texts, and scientific periodicals pertaining to clinical laboratory work and pathology should be maintained, or be readily accessible to the institution.

5. Satisfactory record systems should be provided for all work carried on in the department. Monthly and annual classifications of the work of the department should be prepared.

6. Transcripts of high school and college credits and other credentials must be available. To insure appropriate subsequent registration it is essential that evaluation of entrance credits be obtained from the Board of Registry of Medical Technologists. An acceptable school keeps records of each student's attendance and grades and it is also recommended that the number and type of tests performed be recorded. In addition, the school has a synopsis of the complete curriculum on file, a copy of which is submitted to the Council on Medical Education and Hospitals. This curriculum should include the rotation of assignments, the outline of instruction supplied by the laboratory and a list of the prepared specimens which are used to augment the experience of the student.

7. At least two or more students should be enrolled in each class.

III. Faculty

8. The school should have a competent teaching staff. The director must be a graduate in medicine who is certified in clinical pathology by the American Board of Pathology or who has had training and experience in clinical pathology acceptable to the Council. He shall take part in and be responsible for the actual conduct of the training course. He shall be in daily attendance for sufficient time to supervise properly the laboratory work and teaching.

9. In laboratory practice the enrollment may not exceed two students to each member of the teaching staff. The staff *must* include not less than one instructor whose duties include supervising the teaching program and who is a registered medical technologist (ASCP) or eligible for registration. This is in addition to the laboratory director. In order to be considered as an instructor, a technologist should have had three years of experience while members of the hospital staff or visiting instructors must have regular assignments that cover a complete course prescribed in these Essentials.

IV. Prerequisites for Admission

10. Admission requirements are as follows:

Two years, 90 quarter hours or 60 semester hours, of college work in a college or university accredited by a recognized standardizing association. During the two years the following courses must be taken: (1) Eighteen quarter hours or 12 semester hours of biology which may include general biology, bacteriology, parasitology, physiology, anatomy, histology, embryology, and zoology; (2) Nine quarter hours or 6 semester hours of inorganic chemistry, including lectures and laboratory, and 4 quarter hours or 3 semester hours of either quantitative analysis, organic chemistry or biochemistry, including lectures and laboratory (quantitative analysis is especially recommended); (3) Electives, including English, general mathematics, physics and typing.

V. Curriculum

11. The course of training should be not less than twelve months in duration and should include the following subjects: biochemistry, hematology, bacteriology, parasitology, tissue technique, serology, urinalysis, basal metabolism, electrocardiography, and miscellaneous clinical microscopy.

12. The instruction should follow a planned outline similar to "A Curriculum for Schools of Medical Technology" of the Board of Registry of Medical Technologists and should be accomplished by text assignments, lectures and discussions, demonstrations, supervised practice, quizzes and written, oral and practical examinations.

VI. Clinical Material

13. Each student should receive practice training, adequate in kind and amount, under competent supervision. Participating hospitals should be registered and be otherwise acceptable to the Council on Medical Education and Hospitals of the American Medical Association. Approved schools should have available laboratory material equivalent to that provided by a hospital of 100 beds and 3,000 yearly admissions and a minimum of 35,000 tests a year with a distribution of clinical material sufficient to provide adequate technical training in the various laboratory divisions.

VII. Ethics

14. Excessive fees and commercial advertising should be considered unethical.

15. Schools conducted primarily for the purpose of substituting students for paid technologists will not be considered for approval.

VIII. Health

16. Applicants shall be required to submit evidence of good health and successful vaccination, and a report of a medical examination should be a part of the students' records. This examination shall include a roentgen examination of the chest. Provisions should be made for medical care and hospitalization, when necessary, for a reasonable length of time.

IX. Admission to the Approved List

17. Application for approval of a school for the training of technologists should be made to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois. Forms will be supplied for this purpose on request and should be completed by the director of the laboratory requesting this approval. Inquiries regarding the registration of qualified medical technologists should be addressed to the Board of Registry of Medical Technologists, Post Office Box 1209, Muncie, Ind.

18. Approval may be withdrawn whenever in the opinion of the Council a school does not maintain an educational service in accordance with the above standards. Whenever a training program has not been in operation for a period of two consecutive years, approval may also be withdrawn.

19. Approved Schools should notify the Council on Medical Education and Hospitals whenever a change occurs in the directorship of the school.

REPORT OF THE COUNCIL ON MEDICAL SERVICE

To the Members of the House of Delegates of the American Medical Association:

Progress in Medical Service

Marked progress in the field of medical service for the American people during 1953 is herewith reported by the Council on Medical Service. The Council, working through its seven committees, has conducted numerous studies, surveys, and field trips which point out these advances. In the reports that follow, the Council presents a brief review of some of the specific medical care problems with which it has been concerned. Each of these has its place in a pattern which the Council and its committees are molding into a plan for medical service that can be used as a guide for state and county medical society activities. It will be noted that, in some fields, the Council can give only information; in other areas guides are beginning to develop, and plans are being formulated for medical service programs.

The final solution of some of these problems is not simple. Many are controversial, and because of this the correct procedure in resolving them is in some instances difficult to determine. Despite these difficulties, the following facts from the various reports are highlighted to show continued development in medical service to the public:

Voluntary Insurance.—A total of 91,667,000 Americans were protected against the cost of hospital care at the end of 1952. This represents a 7% increase over 1951. More than 73,161,000 were insured against the costs of surgical expense, a 12% increase during the year. Medical expense protection was enjoyed by 35,797,000, a 29% increase over 1951, and 689,000 persons are now protected by "catastrophic" insurance, a relatively new form of coverage.

Physicians Placement Service.—Another medical service goal is being approached when 43 states can now be reported as having some form of placement service. This is a substantial increase over the 37 states with such programs in 1952.

Indigent Care Programs.—An ever-increasing interest among medical societies in the organization and administration of indigent medical care plans has developed during the past year. Ten articles in regard to various local plans and programs have appeared in The Journal; four more are now ready for publication. A specific step forward in this field are the "Guides for Evaluating Indigent Medical Care Plans," which appear in this report.

Federal Medical Services.—Meetings and regional conferences dealing with veteran medical services are bringing out many facts and figures which will enable the profession to develop plans whereby those veterans with active service-connected disabilities will receive improved total medical care.

Maternal and Child Care.—Surveys conducted in this field are bringing forth much definitive information which would indicate that the best method for assuring medical and hospital care for dependents of servicemen is coordination of existing services and facilities at local levels rather than a national EMIC-type program.

Studies in Prepayment.—Studies are being conducted to obtain physician reaction as to ways and means of improving health insurance plans.

Emergency Call Systems.—Growth in the number of plans continues at a rapid pace and has increased more than tenfold since 1948, at which time 60 plans were reported compared to the 660 plans reported at present.

Grievance Committees.—Some 600 medical societies now have grievance committees; of the larger societies 83% have such committees. A goal of the Council was reached last year when each state society and the Medical Society of the District of Columbia had established grievance committees. The Council hopes that the same 100% goal may be reached by the larger county and city societies within the coming year.

Community Medical Service Programs.—Special surveys on county society medical service activities show an increase all along the line in community medical service programs.

The aim of the Council is to provide ways and means for the state and county societies to supply the best medical service possible to the American public.

Extension of Hospitals and Other Facilities

The Committee on Extension of Hospitals and Other Facilities has had several changes in personnel this yast year. Dr. W. G. Phippen, Salem, Mass., resigned because of ill health. New members appointed were Drs. Cleon A. Nafe, Indianapolis, and Willard A. Wright, Williston, N. D. Others on the Committee are Drs. Ralph A. Johnson, chairman, Detroit; Elmer Hess, Erie, Pa.; Walter E. Vest, Huntington, W. Va.; E. Dwight Barnett, New York, and John W. Cline, San Francisco.

Physician-Hospital Relations

The committee has received few reports of controversies or dissatisfaction concerning physician-hospital relations. This would seem to indicate that such matters are being resolved locally or that the problem itself has diminished. In connection with this it should be noted that a recent survey of 927 component societies shows that only 309 have hospital relations committees, compared to 479 with grievance committees and 432 with emergency call plans. This may indicate a lack of interest in such a committee, or it may mean that many societies see no need for physician-hospital relations committees. In either event unless the situation changes, no special effort will be made to encourage the creation of such additional committees.

Reprints have been made of the Report of the Joint Committee on Hospital-Physician Relationships, adopted by the House of Delegates in June, 1953. The Council has assumed that the report of the Joint Committee is a supplement to the guides adopted in December, 1951, entitled "Relation of Physicians and Hospitals."

Physicians Placement Service

Physicians placement activities by state associations and by the American Medical Association have increased during 1953. States have been encouraged to improve the data on openings, to expand their contacts with sources of physicians, and to work more closely with communities needing a physician. The committee, in turn, has for the first time sought to publicize the services offered to physicians and communities by the American Medical Association and has developed a periodic reporting system for checking on both openings and requests for placements.

Two regional conferences were scheduled during the year. The first was held in Memphis, Tenn., in March, with eight states represented, and the second in Asheville, N. C., in September, with seven states represented. These were working conferences designed to interest the state associations in improving their placement operations and to learn how the American Medical Association placement service might be of most assistance to the states. Both conferences were successful and have already resulted in the organization of placement programs in several states and an increased emphasis on placement operations and problems in a number of others. The committee believes that such regional meetings will also result in a better understanding as to the relationship between the state and American Medical Association placement activities. However, many states still lag in interest and in the operational aspects necessary to an adequate placement program, and the committee will continue with these conferences as suggested in the Mississippi Resolution adopted by the House of Delegates in June. In addition to the regional meetings, the committee has discussed physicians placement service on the programs of the North Central Medical Conference in St. Paul and the Council of New England State Medical Societies in Boston.

During the past two summers the Council has employed medical students to assist in field work relative to physician placement. Last summer visits were made to Virginia, Indiana, Ohio, Missouri, Nebraska, and Tennessee. This summer a Northwestern University Medical School student was assigned to this project and visited the states of Illinois, Michigan, Montana, Mississippi, Texas, and South Carolina. Descriptions of placement operations in six states have appeared in The Journal, and at least four additional descriptions are scheduled for publication in The Journal this fall.

The field work undertaken by the committee resulted in the conclusion that the following were needed: (1) A descriptive pamphlet designed to assist communities in attracting a physician; (2) a method by which communities could be evaluated or rated in reference to need, to attractiveness, and to ability to support a physician would be necessary to estimate accurately the progress in improving physician distribution; (3) specific suggestions for placement program operations must be developed and made to states which do not have adequate programs; and (4) a descriptive pamphlet designed to assist physicians seeking a location in which to practice. The committee has completed the first two of these and is working on the other two.

A pamphlet entitled "A Doctor For Your Community" has been prepared jointly by the Council on Medical Service, Council on Rural Health, and Department of Public Relations. This pamphlet is designed to assist communities seeking a physician and to stimulate the thinking and activities of community leaders into channels which will yield the best results. Copies have been sent to members of the House of Delegates for their perusal. It has been exceedingly well received by state association placement services, deans of medical schools, state medical examining boards, and others interested in physicians placement problems. The committee believes that this pamphlet directed toward the community seeking a physician deals with but one-half of the problem, and that a similar pamphlet directed toward the physician who is looking for a place to practice is a necessary next step. Such a pamphlet is planned for early spring.

A Medical Priority Rating Program has been prepared and submitted to the state medical associations with full knowledge of the many differences between states. However, the criteria on which a physician bases his appraisal of the desirability and medical need of a community are sufficiently uniform to permit their adaptation to any state. In such adaptation the points assigned to items may be increased or decreased to conform to local conditions without altering the basic concept. Encouraging the state associations to use this program in the operation of their placement services is admittedly an experimental step. At the same time it may well serve several purposes: (1) to stimulate communities to analyze their characteristics and facilities from a physician's viewpoint; (2) to encourage state associations in the collection of a certain minimum amount of information on each opening; and (3) to supply the American Medical Association with a valuable differentiation among the communities in the United States listed as needing a physician.

A detailed description of the program was printed in The Journal, Sept. 19, 1953. Reprints are available in the Council office.

Follow-ups have been completed in the last several months on physicians seeking locations, communities and those in the miscellaneous group seeking a general practitioner, and those seeking the services of a specialist. Additional information has been obtained for all listings which previously gave only the name of a contact person. A revision of the assistant and associate listing has reduced that booklet from the cumbersome size to which it had grown to a size convenient to handle. As a result of these follows-ups the statistics on the Placement Service have been brought up to date as indicated in the following paragraphs.

From July, 1952, to July, 1953, the Placement Service has had 622 requests for information from physicians. Of this number, 68 visited the Council office. Most of the requests involved more than one state; therefore, the number of state listings sent in response to requests was much greater than 622. The six states in which physicians seem most interested in locating are Illinois, California, Colorado, New York, Washington, and Oregon. When the state about which information is requested maintains an active placement service, a copy of the questionnaire completed by the physician is sent to the state so that information may be sent directly from that office. In the specialty field the greatest number of requests were for internal medicine, pediatrics, and surgery.

A recent survey of physicians who have requested data on openings from this office shows that 552 physicians have located or taken additional residency or gone into service since July, 1952. Of those physicians who have been heard from in the recent follow-up, 103 physicians have indicated they would like to have their information sent directly to the community needing a physician. Of the 30 who do not wish their name sent out, 6 are still in the Armed Services. At the present time these names have not been sent to communities, but it is anticipated that this procedure will be used in the near future.

There are now 1,732 openings as compared with 2,000 in July, 1952; 119 places were closed as a result of the recent follow-up. Of the 1,732 openings, 1,355 are for general practitioners, 268 for specialists, and 109 miscellaneous (colleges, foreign, industrial, institutions, public health, temporary, U. S. Government, and Veterans Administration). During the period July, 1952, to July, 1953, the Council office received 329 requests directly from communities. When the state association has an active placement service, the request is forwarded to the state office, and the community is so notified. If the state association does not have an active service, the name of the community is placed in the current listing and sent out to all physicians indicating an interest in that state.

In continuing the work with the location on maps of places requesting general practitioners, the 1,355 openings can be classified by the following four population groups:

	1952	1953
Communities up to 1,000 population.............	984	764
Communities from 1,001 to 2,000 population......	248	264
Communities from 2,001 to 5,000 population......	155	165
Communities over 5,000 population..........	144	162

Roughly 75% of the general practitioner openings at present are in communities of 2,000 population or less. There is an approximate 25% decrease in requests from communities with a population of 1,000 or less. Some of these communities listed are of such size and location that they could not support a physician independently but need to share the services with other nearby communities. A medical priority rating would give concrete evidence to these communities as to why they should be dropped from the current listing.

A questionnaire similar to the one used in 1952 concerning state placement service activities was sent out in the late spring of this year. Below are listed the criteria agreed on as necessary for a state to have an active physicians placement service, with a tabulation of the 47 states replying:

	No. of states carrying on in 1952	No. of states carrying on in 1953
1. Maintenance of lists of openings for physicians with adequate data on each opening..	37	43
2. Study of openings and appraisals of need...	25	38
3. Maintenance of lists of physicians seeking locations and of interns and residents who may soon be seeking locations...........	30	40
4. Cooperation with medical schools and hospitals in an effort to interest students, interns, and residents in general practice, in communities needing physicians...........	18	34
5. Assisting communities in developing ways and means of attracting qualified physicians and educating small communities to the fact that they cannot support a physician and would be better off going to a nearby center for medical service......................	20	32
6. Supplying A. M. A. Placement Service with lists of openings either at regular intervals or as openings develop, whichever method the state wishes to follow.................	19	32

The number of states indicating that they supply the American Medical Association Placement Service with lists has increased. Though these states are sending additions to their lists, some fail to notify this office of communities that have obtained the needed medical service. For example, one state indicated that 50 communities listed with their service had been successful in securing the services of a physician during the past year. Yet the last listing received from that state was in May, 1952, with 34 openings. Only one state failed to return a questionnaire this year. One state answered only the first question. The figures in the above table indicate a substantial increase in the state activities. Further evidence is found in the more frequent revision of listings sent by most states and by carbons sent to the Council office of the information given to physicians requesting listings.

Hill-Burton Act

According to the Public Health Service report for fiscal year 1952, upon which the Council's last survey of Hill-Burton construction was based, there were 1,827 projects approved at that time. A year later, the report for fiscal year 1953 shows 2,104 projects approved, an increase of 277. The number of projects completed and in operation has increased from 950 to 1,229, about 58% of the total number approved. The only projects not in operation or under construction are 148 approved during fiscal year 1953. As a measure of the efficiency of the program, three projects approved in 1953 are already in operation and 82 are under construction.

Projects already in operation have added 49,275 hospital beds to the nation's total, while those under construction will add 44,731 more. In addition, 210 health centers have been completed and 99 are under construction.

Estimated cost of all projects approved thus far is $1,688,013,000, with the federal share set at $582,564,000, approximately one-third of the total. This federal expenditure includes 50 million dollars for the fiscal years 1954 and 1955, which had not been definitely allocated at the end of the fiscal year, since at that time congressional action on the program had not yet been completed.

The 83rd Congress extended the life of the act two years; however, the appropriation has been cut to 65 million dollars per year, instead of the 75 million dollars allotted in previous years. This amount is a compromise between the House bill, which would have cut the appropriation to 50 million dollars and the Senate bill, which would have allotted the full 75 million dollars.

Completed projects are located in all states and in the District of Columbia; projects have also been completed in Alaska, Hawaii, Puerto Rico, and the Virgin Islands. So far as can be determined, the program continues to operate fairly and with a minimum of federal interference.

Indigent Care

The personnel of the Committee on Indigent Care has remained the same this year and consists of Drs. H. B. Mulholland, chairman, Charlottesville, Va.; A. J. Bowles, Seattle, Wash.; E. P. Coleman, Canton, Ill.; John L. Lattimore, Topeka, Kan.; E. A. Ockuly, Toledo, Ohio; Dean W. Roberts, Baltimore, and Roscoe C. Webb, Minneapolis. Dr. Joseph H. Howard, Bridgeport, Conn., was a member of the committee until his death, Sept. 28, 1953.

Interest among medical societies in the organization and administration of indigent medical care plans has increased considerably since the committee began its studies two years ago. Articles have appeared in The Journal describing 10 of the studies made by the committee. They have been reprinted as they appeared, and copies have been made available to component medical societies and others interested in this particular subject.

During the summer the Council again assigned a medical student to this committee for field work. Studies were made of the state level organization of the programs in New York, Pennsylvania, and Massachusetts. In addition the committee supplied staff assistance in a statewide study of indigent care in Kentucky. A statistically selected group of 15 counties was visited and a report, containing recommendations for improvement, was made to the Indigent Care Committee of the Kentucky State Medical Association. Although this was a pilot project, it showed clearly a way in which state and American Medical Association committees and staff can work together to accomplish mutual aims. The committee contemplates continuing the studies and their publication in The Journal until it is satisfied that all varieties of organizational and administrative patterns in the field of indigent medical care have been explored.

In December, 1952, the Council submitted to the House of Delegates a set of "Guides for Evaluating Indigent Medical Care Plans." At the last moment, however, these were withdrawn for revision at the request of a joint committee of representatives of the Committee on Indigent Care and the Council on Medical Education and Hospitals. This joint committee has prepared a further draft which is resubmitted at this time. The committee recognizes that these guides may well undergo change on the basis of future experience and as between areas of the United States; however, it is believed they are basically sound and should be reviewed by the House of Delegates at this time.

GUIDES FOR EVALUATING INDIGENT MEDICAL CARE PLANS

These guides represent working data of the Committee on Indigent Care and are not statements of policy of the American Medical Association. They are presented with full recognition that every community will have local problems which may necessitate variations from the suggestions made here. Nevertheless, it is the opinion of the committee that a reasonable evaluation may well rest on the characteristics listed below.

To serve best its purpose an indigent medical care plan should:

1. Make provisions for those necessary services normally available locally to others:
2. Make equal services *and facilities* available to all indigent groups in any given local area;
3. Utilize existing facilities and avoid duplication wherever possible;
4. Wherever feasible, offer free choice of physician in home and office care so as to have continuity of medical supervision for each patient. A patient should have the opportunity to select a physician of his choice or, where available, a teaching facility (facility here refers to teaching hospitals approved by the Council on Medical Education and Hospitals for residency and/or internship or outpatient department of medical schools approved by the Council). Such facilities should accept only such load as is sufficient to meet their needs for clinical material;
5. Develop and use outpatient clinics not affiliated with teaching hospitals and medical schools only when mutually agreeable to the medical profession and the administrative agency involved. Participation in clinics established by agencies responsible for the care of the indigent, other than in hospitals and medical schools, should be open to all physicians in the community qualified to serve in the particular types of clinics;
6. Provide for medical supervision of all medical aspects;
7. Provide reasonable payment to physicians on a basis agreed to by the medical society. The organization of all programs and the method or methods of payment should be approved and reviewed at regular intervals by the local medical societies. Suggested are:
   a. Fee for service in the home, office, and hospital;
   b. Hourly payments in outpatient clinics;
   c. Where the services to an indigent patient are provided by a teaching facility, the teaching facility should be paid on the same basis as individual physicians. Funds so acquired should be used for the advancement of graduate training. If the facility is a teaching hospital organically affiliated with a medical school, such funds should be expended at the discretion of the medical faculty. If the facility is a hospital not organically affiliated with a medical school, such funds should be expended at the discretion of the medical staff of the teaching hospital.
8. Provide for local administration of the medical program for all indigent groups (such as Old Age Assistance, Aid to the Blind, Aid to Dependent Children, and General Welfare cases) by a single agency;
9. Provide for continuous liaison between medical society and administering agency;
10. Give additional consideration to:
    a. Special diagnostic aids.
    b. Preventive medical services.
    c. Health education.
    d. Rehabilitation.
    e. Home nursing as substitute for prolonged hospital care.
    f. Adequate social service coverage.

The principles embodied in these guides are neither new nor are they a departure from past practices; rather they emphasize medicine's continuing interest in the quality of service rendered to the indigent and medically indigent and in the quality of medical education. One of the hallmarks of American medicine has been the blend of services and teaching and this continues to be one of the Association's primary concerns.

TEACHING MATERIAL SURVEY

At the request of the Committee on Indigent Care the Council on Medical Education and Hospitals conducted a questionnaire survey early in 1953 to learn something of the relationship between indigent medical care and teaching material needed in the field of medical education. The decision to make the survey resulted from joint meetings between representatives of the Council on Medical Education and Hospitals and representatives of the Committee on Indigent Care. These meetings were called to discuss the possible effect on teaching programs of any widespread coverage of the indigent through voluntary health insurance plans. The representatives of both groups were concerned with the extension of voluntary health insurance to cover more and more of those persons who normally go to teaching hospitals for care but who, if given a free choice of hospital, might select a private nonteaching facility. This survey, participated in by 58 of the approved four-year medical schools, indicated that a shortage of clinical teaching material is not a pressing problem for most of the nation's medical schools. In general the majority of the schools have not suffered a reduction in the number of teaching beds nor do they seem to feel that any foreseeable reduction in the number of such beds will seriously impair the teaching program. In other words, the voluntary health insurance program with over 91 million persons carrying some sort of hospitalization insurance has not had an adverse effect on the teaching programs of medical schools. However, the indigent per se have not with the exception of a few areas been included in voluntary health insurance plans, and the question of the effect of any widespread inclusion of this group under voluntary health insurance still remains unanswered.

Copies of the report of the teaching material survey have been sent to the deans of the medical schools for their information, and the joint committee will continue to follow any developments and report them to the House.

Maternal and Child Care

The personnel of the Committee on Maternal and Child Care has changed somewhat during the year. Dr. W. F. Mengert, Dallas, Texas, resigned for health reasons and Dr. Stanley R. Truman, Oakland, Calif., resigned to serve on the Joint Commission on Accreditation of Hospitals. New members appointed during the year are Drs. Harold S. Morgan, Lincoln, Neb., and Philip S. Barba, Philadelphia. Other members at present are Drs. W. L. Crawford, Chairman, Rockford, Ill., H. B. Mulholland, Charlottesville, Va., Garland D. Murphy, El Dorado, Ark., and Donald A. Dukelow, Bureau of Health Education, American Medical Association, Consultant.

The committee completed its studies relative to maternal and child care for the dependents of servicemen early in 1953. As has been reported previously, these studies were made in Los Angeles by the Welfare Council of Metropolitan Los

Angeles. They have been reported on in THE JOURNAL in three separate articles (June 7, 1952, June 20, 1953, and Sept. 5, 1953). Two of these articles described the contents of the studies, and the third contains the recommendations of the committee which were made directly to "the Los Angeles County Medical Association, the Welfare Council of Metropolitan Los Angeles, and such other local agencies as are concerned with providing medical and hospital care to the wives and dependents of servicemen." The full statement concerning these recommendations is too long to be reproduced in this report. However, because of the recent report of the Citizen's Advisory Commission, appointed by the Secretary of Defense, which recommended that dependents of servicemen be provided with medical and hospital care at Federal expense, the House of Delegates should be aware of the fact that this Committee has gone to considerable lengths to inform itself on the subject of medical and hospital care for dependents of servicemen. At no time in this study has the Committee or the Council been convinced of any widespread need for a national program to provide medical and hospital care for this group. On the contrary, the only realistic approach to the problems encountered is, the Committee believes, through local physicians, local hospitals, and local agencies working jointly together to provide such care and services as are necessary. In its studies the committee assumed that "the dependents of our military men, particularly of those who are drafted into the service, constitute a group whose age, income, and frequently transient status are such as to warrant special consideration on the part of civilian agencies concerned with medical, hospital, and related services." And yet, in these studies, the committee found that the health problems of this group are often such that related services, such as counseling, day care, homemaking, and other similar services loom larger in importance than do physician and hospital services. In the solution to such problems, coordinated activity is far more necessary than the type of national program recommended by the Advisory Commission.

It is recommended to the House of Delegates that that portion of the report of the "Citizen's Advisory Commission on Medical Care for Dependents of Military Personnel" that has to do with maternal and child care be opposed and that the Department of Defense be made aware of the work and conclusions of this committee. In brief, the commission recommended that among other medical services, maternity and infant care should be provided to all dependents of servicemen as a matter of sound personnel policy. This care, wherever practicable, is to be provided in military medical facilities, although special arrangements are made for emergencies and dependents who live more than 25 miles from such military facility. The Commission's recommendations are such that the extent of coverage and the governing rules and regulations will result in a program much greater in scope and extent than the EMIC program of World War II.

It is requested that the House of Delegates urge the Los Angeles County Medical Society to make every effort to implement the recommendations which were made by the Committee.

Finally, it is urged that the House of Delegates commend these recommendations to all county medical societies so they may be used as guides whenever the need arises to take action regarding medical and hospital care for dependents of servicemen.

During the past several years, the Committee on Maternal and Child Care has concerned itself primarily with the problems of providing medical care to dependents of servicemen. Unless new circumstances require it, the committee will in the future devote itself to the general subject of maternal and child care. It has the opportunity to be one of the driving forces for further improvement in this field and anticipates functioning as a coordinator endeavoring to maintain liaison in the whole field of maternal and child health among the American Medical Association and other agencies concerned. It will seek to enlist the cooperation of all official and voluntary organizations working toward the same end. It will work with and through county medical societies to determine what communities are doing in this field and in the development of guides, standards, suggested programs, and other material which may be useful to the individual physicians, medical societies, and others interested in improving maternal and child care.

Medical Care for Industrial Workers

The Joint Committee on Medical Care for Industrial Workers of the Councils on Industrial Health and Medical Service has had only one change in personnel during the past year. Dr. Robert Homan, El Paso, Texas, has filled the vacancy created when James Q. Graves, Monroe, La., left the Council. Other members are Drs. W. A. Sawyer, chairman, Rochester, N. Y.; Warren F. Draper, Washington, D. C.; Edwin P. Jordan, Charlottesville, Va.; Raymond F. Frech, Newton, Iowa; Leo Price, New York; Clark Bailey, Harlan, Ky.; Frederick W. Slobe, Chicago; and consultants Fritjof Arestad, Donald A. Dukelow, and Carl Peterson, of Association headquarters.

The committee has continued to follow developments in regard to temporary cash sickness benefits legislation, not only in those states which have such legislation (Rhode Island, California, New Jersey, and New York) but also in other states as their legislatures have met. Since 44 state legislatures meet in the odd-numbered years, 1953 necessarily provides considerable data on this subject. Although no bills introducing a new program were passed during the year, the number and types of legislative proposals submitted indicate the continued persistence of the proponents of such programs. This persistence, however, was not as widespread as in 1951. In 1953 new cash sickness benefits bills were introduced in only 11 states compared with 16 states in 1951. The number of such proposals also decreased from 40 in 1951 to 31 in 1953. The greatest activity seemed to be centered in three states. These are Massachusetts with 12 bills, Connecticut with 6, and Minnesota with 4. Amending legislation, in the four states where temporary disability programs are in operation, showed clearly that the original form of legislation can be altered substantially. The total number of amendatory bills was less this year than in 1951, with 123 proposals compared to 144 two years ago. The scope of these proposals, however, was the same as in previous legislative years, embracing almost every conceivable type of expansion concerning benefits, time covered, waiting periods, and persons covered.

Again, as in previous years, no recommendation as to policy is made. The Council's committee will continue to follow developments and, on request, will be prepared to provide information to states interested.

STUDY OF UNION HEALTH CENTERS

The first phase of the study of organized programs of medical-hospital care for industrial workers provided through unions, management, and employee benefit groups has been completed. A booklet has been prepared for publication containing short descriptions of the organization and operation of 12 of the union health centers. These 12 represent both C. I. O. and A. F. of L. unions and are located in six different states. The discussions in the booklet are designed to provide information on the following categories: history, membership, objectives, facilities, financing, budget and operating costs, administration, business and professional personnel, benefits, and preventive aspects of the services. No effort is made in the booklet to evaluate these plans, although the committee believes that some expression in this regard is necessary and plans to undertake such a project. In addition to the booklet on union health centers, an article has been prepared and submitted to THE JOURNAL for publication. This article will deal generally with the characteristics of the 12 union health centers studied and will include such specific data as is suitable for compilation in table form.

The second phase of the study will have to do with the management or employee benefit sponsored plans. A number of the individual plants have been visited and data already compiled. Additional field visits are planned for this winter and early spring in order to complete a second booklet before the House of Delegates meets in June.

It should be reiterated here that this study is primarily concerned with independent, nonmedical-sponsored plans (not Blue Shield, Blue Cross, or private insurance), which provide medical and/or hospital services for nonoccupational illnesses. Such plans also provide what is generally spoken of as "service benefits" as opposed to "cash" or "cash indemnity" benefits. Most of these programs maintain their own clinic facilities and employ physicians either on a full-time or part-time basis. Their importance to the House of Delegates and to individual practitioners generally is not in their newness but rather in the increasing interest that organized labor has shown in them. Just what place these plans will play in organized medical programs depends on their acceptance by the persons whom they serve and the individual physician who serve them.

UNITED MINE WORKERS

In December, 1952, the Council reported in detail on the activities of the Committee on Medical Care for Industrial Workers in relation to the UMWA Welfare and Retirement Program. In the spring of 1952 the committee sent a survey team into the bituminous coal mining areas to review the conditions there, and in September, 1952, sponsored a conference to which were invited representatives of the five state medical associations in that area and representatives of the area medical offices of the UMWA Welfare and Retirement Program. The recommendations of the survey team, and of the conference as well, have been reported on in detail in THE JOURNAL.

In September, 1953, the committee sponsored a Second Conference on Medical Care in the Bituminous Coal Mine Areas, again in Charleston, W. Va. The meeting was attended by over 70 representatives of the five states concerned (Kentucky, Tennessee, Pennsylvania, Virginia, and West Virginia), by representatives of the Area Medical Offices of the UMWA Welfare and Retirement Fund, and by other invited guests. The purposes of this second conference were as follows:

1. To review the recommendations made at the first Charleston conference with reference to improving medical service in the bituminous coal mine areas;
2. To adopt, revise, or reject these suggestions and recommendations;
3. To discuss ways and means of implementing those recommendations that are acceptable; and
4. To bring to light such constructive positive activities as have been undertaken within the last year to improve medical-hospital conditions in this area.

For the purpose of discussion the problems considered fall within one of the following categories: Medical practice, recruitment and training of physicians, medical and hospital facilities, health education, and organization and function of liaison committees. The conference participants were divided into five groups corresponding with these categories and spent the better part of two days reviewing these general subjects as they pertain to medical and hospital care in the bituminous coal mine areas. A full report of the conference will be submitted to THE JOURNAL for publication.

RESOLUTION ON UMWA WELFARE AND RETIREMENT PROGRAM

In June, 1953, the House of Delegates referred to the Council on Medical Service a resolution referring specifically to the UMWA Welfare and Retirement Fund and requesting "That the American Medical Association, through its proper committees, immediately study this problem in order to ascertain the true objectives and methods of operation of all health and welfare funds."

At the time of the second Charleston conference the Committee on Medical Care for Industrial Workers met with representatives of the Medical Society of the State of Pennsylvania and of the UMWA Welfare and Retirement Fund and discussed at length the problems which motivated the above-mentioned resolution. As a result of that conference it is believed that better understanding of the various factors involved have been attained by all parties concerned. In regard to the request to study "all health and welfare plans," the Council would inform the House of Delegates that its Committee has been studying union health programs for the past year and will continue these and other studies until sufficient data have been gathered on which to suggest a policy. Two steps have already been taken to inform the medical profession of developments in this field—an article describing 12 union health plans has been prepared for publication in THE JOURNAL, and a pamphlet containing full data on their organization is to be published for distribution to interested persons.

Federal Medical Services

The personnel of the Committee on Federal Medical Services has remained the same since the last report and consists of Drs. Louis M. Orr, chairman, Orlando, Fla.; J. D. McCarthy, Omaha; C. B. Puestow, Chicago; Richard L. Meiling, Columbus, Ohio; Harvey B. Stone, Baltimore; Vincent W. Archer, Charlottesville, Va.; Curtis Lohr, Clayton, Mo., and consultants Dr. Frank E. Wilson, Washington, D. C., and Mr. J. W. Castelucci, Detroit. In order to maintain continuous liaison with other association councils, Dr. Edward R. Leveroos, associate secretary, Council on Medical Education and Hospitals, and Mr. C. Joseph Stetler, Secretary to the Committee on Legislation and the Council on National Emergency Medical Service, have been invited to meet with the Committee.

During the first part of 1953 this committee was concerned with laying the groundwork for a general study of federal medical services. The prepared study was approved by the Board of Trustees in February. The committee met in March to review the subject matter involved and to arrange for proper relationship and cooperation during the study with the Secretary's Office, the Washington Office, the Council on Medical Education and Hospitals, and the Council on National Emergency Medical Service.

The staff has briefly reviewed all departments and divisions of the federal government as well as those multilateral international organizations in which the United States participates. The purpose of the review was to learn which federal agencies have activities concerned with health and medical services. In order to learn something of their scope and extent, these activities have been classified under the following headings: (1) Yes, indicating some definite program of medical service; (2) Minor, indicating a small medical service program or services associated with medical care; (3) Advisory, indicating no actual service, research, or grant program, but that the agency advises on health or medical matters; (4) Control, indicating some measure of control is exercised over health matters or services, although none are provided, and (5) Cooperating, indicating that the agency cooperates in some type of medical service programs provided by another agency.

After the various health activities of the federal government were classified under these five headings they were tabulated under the four major divisions of the government; that is, the judicial branch, the legislative branch, the executive branch, and the multilateral agencies. Having learned that 83 of the federal agencies have some concern with medical or health services, these were then reclassified as to type of service under the following headings: (1) maintenance, (2) care, (3) combination, (4) research, (5) grants, (6) supervision, (7) employee, (8) control, (9) investigation, and (10) policy. It is interesting to note that 36 of the agencies having some concern with medical or health services are "independent" agencies of the federal government and do not fall within the 9 basic departments.

Realizing that this is not something that can be done quickly, the committee is still working on the following questions: 1. Which agencies should be given detailed consideration? 2. What is the scope of the information and data to be collected? 3. What are the best methods for collecting data and information in such studies? 4. What of the possibility of using private research agencies? 5. What type of timetable and priority system should be developed for the study?

VETERANS MEDICAL SERVICES

The entire problem concerned with veterans medical services and the policy adopted by the House of Delegates in June concerning non-service-connected disabilities was referred to the Committee on Federal Medical Services after the Annual Meeting. The first project of the committee in this regard was the revision of the Survey of Federal Medical Services. In the light of the June policy statement and in order to direct attention specifically to that portion of the policy having to do with non-service-connected disabilities, a second pamphlet has been prepared and published entitled Medical and Hospital Care of Veterans with Non-Service-Connected Disabilities.

Recognizing the need for understanding of the basic principles and problems involved on the part of state medical association officers and of individual physicians, a special meeting was held in Chicago on Sept. 1. To this meeting were invited representatives of all the state medical associations with a specific request for representation from state committees having to do with the problem of veterans' medical care. The conference was attended by some 95 persons representing 38 state medical associations and gave the committee an opportunity to learn something of the opinion of the constituent medical societies concerning the American Medical Association policy relative to non-service-connected disability cases.

When the House of Delegates adopted the policy statement in June, it also adopted the following recommendation of the Reference Committee " . . . that all of the facilities of the American Medical Association and of its constituent state and county societies be employed immediately to disseminate background information and accurate statistical data in this regard. Every effort should be made to inform the profession and the public concerning the nature of the problem, the position of the American Medical Association, and the reasons on which that position is predicated."

The conference was the first step in carrying out this recommendation. A second step undertaken by the committee is a series of regional conferences throughout the United States. The first four are planned for New York, Washington, Atlanta, and Dallas and will have been completed by the time the House meets in December. The purposes of these conferences are (1) to develop a working liaison with state association veterans' committees; (2) to discuss methods for carrying out the instructions of the House of Delegates; (3) to increase the number of physicians who have a working knowledge of the policy and the facts relating to it; and (4) to learn the situation in each state. On the basis of these conferences the Council will submit a supplementary report to the House in December relative to future activities designed to carry out the above recommendations.

Prepayment Medical and Hospital Service

The Committee on Prepayment Medical and Hospital Service has had two regular meetings since the last formal report. Dr. Lewis A. Alesen, Los Angeles, was named to the committee to fill the vacancy caused by the resignation of Dr. E. Vincent Askey, Los Angeles. Subsequent to his election to the Council, Dr. Carlton E. Wertz, Buffalo, N. Y., was named as the Council member of the committee. In keeping with the plan of having six committee members in addition to the Council member, Dr. O. B. Owens, Alexandria, La., was named as a new member. The other members of the committee at present are Drs. Percy E. Hopkins, chairman, Chicago; Carl F. Vohs, St. Louis; Thomas J. Danaher, Torrington, Conn., and Harold E. Nichols, Seattle.

VOLUNTARY HEALTH INSURANCE

In its last annual report to the House of Delegates the Council estimated that over 90 million persons would be protected by some form of voluntary health insurance at the end of 1952. It is encouraging to report that this estimate was valid, and that the final figures as gathered by the Survey Committee of the Health Insurance Council indicated the correct estimate to be 91,667,000. The total number of persons insured under the separate categories of hospital, surgical, and medical expense benefits were as follows: hospital, 91,667,000; surgical, 73,161,000, and medical, 35,797,000.

The number of persons enrolled in voluntary health insurance plans which are either approved or sponsored by medical associations or coordinated with local hospital benefit plans increased during 1952 to a total of 27,686,575. This represents an increase of 3,720,694 over the figure of 23,965,881 at the end of the previous year. During the current year one plan which had been approved since its inception by a medical association reinsured all of its liabilities with a local insurance company.

The health insurance brochure was revised again this year, and the title was amended to "Voluntary Prepayment Medical Benefit Plans." This title was deemed more appropriate since the booklet describes benefits rather than medical care. Copies of the brochure and the supplemental pamphlet "Charts and Graphs" were mailed to all members of the House of Delegates and officers of the Association. Also, copies were mailed to the plans listed in the brochure, offices of constituent associations and component societies, medical schools, and hospitals affiliated with medical schools. In addition to the regular mailing, copies are sent in response to requests from individual physicians as well as requests from organizations and interested individuals.

In past years a copy of the "Annual Survey of Accident and Health Coverage in the United States" has accompanied the Council publications. This year that publication was not ready for distribution at the time of the Council mailing and was sent to a part of the mailing list at a later date. Another Council publication which has continued to be in demand is "Growth of Voluntary Health Insurance." This pamphlet, revised again this year, contains features from the Council brochure and the annual survey. It is written in non-technical language and is available on request.

As in the past, the Committee on Prepayment Medical and Hospital Service contributed to the efforts of the Survey Committee of the Health Insurance Council. The most recent report of the Health Insurance Council shows the following number of persons insured at the end of 1952 by type of benefit and by type of underwriting agency:

	Type of Benefit		
Type of Underwriting Agency	Hospital	Surgical	Medical
Medical society-approved and/or Blue Cross	43,475,000	27,773,000	18,321,000
Insurance companies (group & individual)	51,709,000	48,817,000	15,275,000
Independent plans	5,364,000	4,794,000	5,150,000
Grand total	100,548,000	81,384,000	38,746,000
Deduction for estimated duplication	8,881,000	8,223,000	2,949,000
Net total	91,667,000	73,161,000	35,797,000

The figures for medical society approved plans include enrolment in Blue Shield plans, and those enrolled under independent plans include programs sponsored by industry, university health plans, consumer-sponsored plans, and private group clinics.

An added feature of the latest Health Insurance Council survey was an effort to determine the number of persons protected by catastrophic insurance benefits, sometimes called major medical expense coverage. This type of insurance differs from earlier experiments in that the insured person is normally expected to pay the initial expenses incident to health care. Beyond this initial, deductible portion of the costs the insured may also be required to participate on a percentage basis in the further costs of health care up to a specified maximum limit. In other words, this approach combines the feature of deductible insurance and the principle of co-insurance. Another basic difference between this type of insurance and the earlier experiments is that benefits are paid on a nonscheduled basis. Benefit payments are made in accordance with the charges for professional, hospital or ancillary services, and normally the only qualifying feature is that the insured is to be reimbursed for such charges as are usual and customary for those services in the area in which they are rendered. Although this particular form of insurance is newer than the others and has certain inherent administrative problems, it was estimated that 689,000 persons had this type of protection at the end of 1952.

SEAL OF ACCEPTANCE

The Seal of Acceptance program continues to be of interest, and an attractive certificate has been prepared to issue to those plans which have been awarded the seal. In keeping with the review schedule originated earlier this year the Committee on Prepayment Medical and Hospital Service is continuing its periodic review of those plans which have been awarded the seal. New applications for the seal continue to be submitted together with supporting data as more plans realize that this is a necessary procedure. The seal is extended only in those instances where an expression of interest is manifested, when formal application is made, and when in the opinion of the committee and the Council the plan satisfies the requirements outlined in the Standards of Acceptance.

SIMPLIFIED CLAIM FORMS

Continued interest is being expressed from several quarters concerning the further use of simplified reporting forms by insurance companies when medical or hospital information is sought to enable the companies to audit claims. The content of the resolution introduced at the 1952 clinical meeting relative to the more widespread use of simplified claim forms has been conveyed to the Health Insurance Council. The Health Insurance Council has appointed a special committee to deal with this problem. That special committee now has several types of claim forms under consideration. Among them are hospital expense, attending physician's statement (including necessary information for payment of surgical benefits), loss of time, individual and group life as well as total and permanent disability insurance claim blanks. The special committee is apparently continuing the efforts initiated earlier by the International Claim Association and the Health and Accident Underwriters Conference. Several years ago those organizations prepared several simplified claim forms including the two Attending Physician's Statement forms which were approved by the Council. It is reported that progress has been made regarding some of the other forms, and it is possible that a few of them will be revised and ready for consideration before the end of the year.

Special Studies

Since the last annual report the Council authorized its Committee on Voluntary Prepayment Medical and Hospital Service to name a special committee to consult with a committee named by Blue Shield Medical Care Plans Commission. That authorization was an outgrowth of proposals which had been reviewed by the Council relating to realms which might be of mutual interest to the two organizations, such as physician attitudes concerning service benefits, coinsurance, etc. These two committees have had several meetings and have collaborated in the development of a questionnaire designed to learn the attitudes of physicians concerning certain aspects of voluntary health insurance. Independent opinions were sought in devolping the questionnaire so it would produce a minimum of misinterpretation among those receiving it and, at the same time, supply credible data not heretofore compiled. The survey itself is under the supervision of the Council and its committee. A sufficient sampling has been planned with a view toward providing data which will be valuable to both the medical profession and the various agencies which underwrite insurance to help pay the costs incident to health care.

After the completion of the current survey further studies are contemplated by the Council and its committee. It is hoped these later studies will ultimately permit a qualitative analysis of some of the quantitative surveys that are conducted on an annual basis. In planning these undertakings it is hoped that other groups, including the Blue Shield Commission, the Blue Cross Commission, and the Health Insurance Council will participate.

Relations with Lay Sponsored Voluntary Health Plans

The present membership of the Committee on Relations with Lay Sponsored Voluntary Health Plans is as follows: Drs. Frank J. Elias, Chairman, Duluth, Minn.; Robert B. Homan, El Paso, Texas; H. Russell Brown, Waterloo, S. D.; George S. Klump, Williamsport, Pa.; James Stevenson, Tulsa, Okla., and Mr. C. H. Crownhart, Madison, Wis.

This Committee has had a series of meetings since the last annual report. As a result of those meetings, the Committee is considering a number of annotations to the "Suggested Principles for Lay Sponsored Volutary Health Plans." The Council submits this as a progress report and will submit a further report at a later date.

Professional Liability Insurance

For several years the Council has concerned itself with many nonlegal phases of professional liability insurance. The House received a resolution at the last annual meeting concerning the practice by certain insurance companies of making extra premium charges when those companies provide coverage to physicians who are members of partnerships. That resolution was referred to the Council on Medical Service.

Two resolutions concerning professional liability insurance were introduced during the 1952 Clinical Meeting. They were from the District of Columbia and Mississippi and are quoted respectively as follows:

Resolved, That the Board of Trustees of the American Medical Association be directed to make an immediate study of the professional liability insurance situation and submit its findings to the House of Delegates at its next meeting, in the meanwhile taking such action as may be appropriate.

Resolved, That the House of Delegates require a continuing study and monitoring of developments in this type of insurance to the end that the interests of the membership may be adequately safeguarded in this vital underwriting service.

The House approved the recommendation of the reference committee that ". . . the Board of Trustees . . . direct the appropriate Council or Bureau to make a continuing study . . . and submit a progress report to the House of Delegates at its next meeting." The Board of Trustees referred those resolutions initially to the Council on Medical Service. To the end that these studies may be more comprehensive they are being continued by the Council staff in cooperation with the staff of the Bureau of Legal Medicine and Legislation.

A progress report was made to the House by the Board of Trustees at the Annual Meeting in June. The studies are in progress and will require a great deal of time since the necessary data, for the most part, have not been maintained on any uniform basis over the years. The resolution concerning the practice of charging extra premiums for partnerships has been included in the scope of the studies. At such time as the Council is in a position to make a more definitive report to the Board it will include this aspect in order to minimize the number of reports addressed to the House concerning the same general subject.

County Society Activities Survey

In 1948, the Council conducted a pilot survey of county medical society activities, covering some 200 societies. A second survey, published in 1951, went into greater detail and covered 757 societies, over one-third of the nation's total. In March, 1953, the Council sent questionnaires to all of the 1,932 (estimated) component societies, basing the questions not only on previous surveys but on additional data and new activities which had come into prominence in the interim. By the time tabulation for the report was begun, 927 replies had been received. The survey therefore covers almost half the nation's societies; its value as a cross section is indicated by the fact that over 85% of the societies, including almost 90,000 physicians, with 100 or more members are represented, and over 40% of the societies with less than 100 members. Geographically also, the survey is a cross section, since replies were received from every state in the Union, as well as from three Hawaiian societies. Actually 1,400 counties are represented since 180 of the societies cover more than one county. The multi-county societies generally represent sparsely settled sections of the country, where one county does not have enough physicians for an active professional organization.

The report covers four general subjects: meetings, activities, personnel (paid employees), and finances, thus providing data on almost every phase of society operation. The data on meetings include tabulation of the frequency of meetings, percentage of attendance, and popularity of subjects.

Activities, the major subject of the report, are broken down into four types: (1) *Society Programs*, dealing with the society's professional relationship with the patient and with other community agencies; (2) *Public Education Programs*, dealing with the interpretation of the society's medical and socio-economic activities to the general public; (3) *Community Programs*, dealing wtih the society's formal or informal participation in programs sponsored by voluntary or governmental agencies; (4) *Group Insurance Programs*, dealing with the various types of insurance coverage available to society members as a group through the county society or the state association.

The section on personnel provides data not only on the number of societies with executive secretaries but also on the number of other employees on society payrolls. The section on finances shows the amount of dues per society for 1953 as contrasted with 1942, the number of societies increasing or decreasing their dues and the number which made special assessments during 1952.

In the earlier surveys, replies were tabulated in four groups, according to the number of members: I—less than 100 members; II—100 to 200 members; III—200 to 300 members; IV—over 300 members. The 1953 replies have been tabulated in six groups, with the first three covering societies with 0-14, 15-49, and 50-99 members respectively, and groups IV to VI the same as II to IV in the previous surveys. It was felt that the variation in activities with the size of the society in groups with less than 100 members is greater than that between societies of 100 and 300 members. The more detailed tabulation, therefore, provides a much clearer picture of the increased activity which accompanies an increase in the number of members. In general, the survey shows that the larger societies have more activities, as might be expected, and a lower percentage attending meetings. The only major increases since the 1951 survey are in emergency call plans and grievance committees, these being activities on which much emphasis has been placed in recent years. Insurance coverage has also increased, as have dues, although only to a slight extent.

The survey indicates that most societies which have sufficient members to engage in organized programs take seriously their obligations both to their patients and to the community at large.

Emergency Call Plans

The growth in the number of emergency call plans continues, and many county societies report that this program has been one of the most effective public relations aids of all the society's activities. From the 60 plans reported in 1948 and the 364 reported in the Council's 1951 survey of county medical society activities, the total number of plans reported had risen to over 660 by the end of 1952. Even this figure is probably less than the actual total of plans in operation, since the 1953 survey of county society activities based on replies from approximately half the nation's component societies shows a total of 432 formal plans. If the same proportion of coverage holds true for societies not replying well over 800 such plans may be postulated. Further growth, however, will probably be much less rapid, since almost all the larger societies now have such plans. Those without formal plans are usually the smaller societies which must depend on informal arrangements by or among individual physicians to provide coverage for patients in the community.

Studies made by individual societies of the calls received indicate that there is little abuse of the service by the public. The majority of calls answered seem to be either actual emergencies or sufficiently serious to warrant the patient's urgent concern. The main difficulty encountered, according to reports from many societies, is a lack of volunteers from the society membership to handle calls. In an increasing number of societies, this problem is being met by a compulsory duty roster whereby all members not exempt by age or physical disability take their turns in treating emergencies. Reports indicate that some physicians believe they may endanger their specialty ratings by handling emergency calls outside their field. However, the great majority of the American Boards agree that the specialist is a physician first when an emergency arises. At the last report, only three boards had not agreed that their members might participate in such plans.

Grievance Committees

Since the 1949 resolution of the House of Delegates concerning the establishment of grievance committees to hear complaints from the public, the Council has studied and urged the development of such committees. In 1952 the Council published a detailed study of the organization and operation of state association committees. This year, 1953, a complementary study of county society committees was published, based on data provided by 198 societies.

At present, all but three states handle complaints either through a committee especially appointed for this purpose or through the Council of the association; the three without such a body have decided that such complaints should more appropriately be considered by the local society. The most recent tabulation of county society committees shows almost 600 societies providing for the hearing of complaints. However, the 1953 survey of county society activities shows over half the societies reporting maintain such a body so that the total at present may be much larger. Among the larger societies, that is, over 200 members, 83% have such committees. This percentage decreases as the size of the societies decrease.

The title, "grievance committee" is by far the most popular, although some 39 other titles are also used. The House of Delegates, in its December, 1952, session, recommended that the Council study the matter of names of these committees. As a result of this study, which showed approximately 60% of the societies using the word "grievance" in the committee title, it would seem that most societies consider this the name best expressing the committee function and most easily understood by the layman. A full report on this was made to the House in June, 1953.

The Council's report on county society committees provides a detailed examination of all facets of committee operation. Among the points considered are membership, meetings, jurisdiction and procedure, complaints received, operational methods, and public relations. A number of tables show the variations in method in relation to the size of the society.

An experiment reported by 10 societies concerning the inclusion of lay members in the committee, may be an important development in society public relations. While the policy of using non-medical representation has had rather widespread acceptance in the prepayment plan field, it is rarely found in the standing committees of medical societies. However, a number of such committees now have functions which tend to make them quasi-public, and it may be that lay or non-medical representation can serve to emphasize the profession's interest in public policy.

Another interesting highlight of the report is the fact that more than one-third of the committees will attempt to settle complaints against nonmember physicians. Although the society, of course, has no jurisdiction over these physicians, their actions, in the public mind, reflect on the whole profession. The society, therefore, attempts to arbitrate such grievances as well as those directed against its own members.

Group Practice Study

World War II brought with it a new interest in the formation of clinics and in group practice itself. As a result, the Council on Medical Service received many requests from physicians interested in organizing a group clinic and inquiring into the many problems involved in such a venture. To assist in this, a group practice loan kit was prepared and used in replying to inquiries on the subject. Although the loan kit has been revised and expanded at intervals during the past few years, it has been impossible to obtain sufficient information from existing published material to provide adequate data for those interested in organizing a group practice unit. In view of this and as a result of conversations with representatives of the American Association of Medical Clinics, it has been decided that the two groups will jointly sponsor a survey of the organization and operation of various types of group practice clinics in the United States.

The purpose of the study is "to develop practical information for the benefit of physicians desiring to start a group practice or for those already in a group practice who wish to alter or improve their existing arrangements." The group practice units selected are to be representative of medium and small groups rather than large groups and are to be located in small communities, medium-sized cities, and areas adjacent to large cities, since most of the interest in group practice is directed toward such areas. A prospectus containing pertinent questions designed to elicit the information necessary to accomplish the purpose of the study has been prepared and approved by both the American Association of Medical Clinics and the Council on Medical Service. No specific time deadline has been set for the completion of the study, but it is hoped that the field visits can be completed by early spring and a report can be made to the House of Delegates at the annual meeting in June, 1954.

REPORT OF THE AMERICAN MEDICAL EDUCATION FOUNDATION

To the Members of the House of Delegates of the American Medical Association:

This, the third report of activity by the American Medical Education Foundation to the House of Delegates of the American Medical Association, marks the 31st month of continuous effort on the part of the officers, directors, and working committees of the Foundation to develop a new and continuing source of income for the nation's medical schools. This program in philanthropic financing, in cooperation with the National Fund for Medical Education, has produced $4,764,052.64, which has been distributed in the form of unrestricted grants to the 79 approved medical schools. While still short of the amount needed annually, these funds have assisted materially in the schools' fight to regain financial solvency, without resorting to federal subsidy. The medical profession has supplied approximately 48% of the total funds raised to date.

Unquestionably the growing acceptance of the Foundation's program by the medical profession can be traced largely to the continuing financial assistance given by the American Medical Association during the past three years. The latest grant of $500,000 brings the total contribution of the American Medical Association to $1,500,000. Without these funds the Foundation would not have progressed to its present position for many more years. The Foundation now stands on the threshold of future success and with the renewed support of the American Medical Association, the realistic goal of 2 million dollars can be attained. The officers and directors view the future with considerable optimism.

In addition to the $500,000 grant from the American Medical Association, during the first seven months of the current year, the Foundation has received contributions from individuals and organizations which swelled the total income to $839,824.37; this is approximately 12% more than was received during the same period in 1952. The number of contributors to the Foundation during the first seven months of 1953 exceeds the total number of contributors in 1952 by more than 92% (13,259 as compared to 7,259 in 1952).

At the June, 1953, meeting, the Board of Directors voted to transfer all accumulated funds of the Foundation to the National Fund for Medical Education as of the close of business June 30, 1953. On that date, the sum of $1,044,602.47 was transferred. It represents the total income of the Foundation for a 12 month period—June 30, 1952, to June 30, 1953. It also represents more than 50% of the total funds distributed by the National Fund in its fourth round of grants to the nation's medical schools. The National Fund made grants totaling $1,944,151.64 during July.

During November, 1952, the Foundation made its first mass mailing to the medical profession. The mailing consisted of a specially designed tax folder which pointed up the value of making a contribution to the Foundation. The mailing was made at a total cost of $9,600 including first-class postage and returned more than $60,000 in 1,600 contributions. In addition to adding dollars and contributors to the Foundation, it served an added role of telling once more the story of the Foundation's program to help the medical school. Another mailing of this type is planned for the same time in 1953 and many state and local campaigns are being tied into it so that they may take advantage of the added impetus of a national direct mail effort.

The Foundation's exhibit will be shown at 12 state and local medical society meetings during the current year, as well as at the annual and clinical meetings of the American Medical Association.

Visits by officers, directors, and the executive secretary were made to 12 state medical society annual meetings, and such visits are scheduled to bring the total to 21 before the end of the current year. In addition to these trips, many special trips have been made by Foundation personnel to various states to assist in the organization of committees, preparations of materials, and conducting conferences relating to the state campaigns.

Approximately 100,000 pieces of promotional material have been distributed through the medium of the state and local campaign committees as well as the state medical societies. Again, the editor and staff of THE JOURNAL have given every assistance in the preparation and publication of editorial material relative to the progress of the Foundation. The Foundation has received space in THE JOURNAL for institutional advertising as in the past. In addition, all state and county medical society editors and executives are to be commended for their continued cooperation during the current year. The Foundation has made use of a news letter type bulletin at regular intervals to keep all personnel concerned with the operation of the program alerted to the many changes which take place during day-to-day operation of the campaign.

The Woman's Auxiliary to the American Medical Association has redoubled its efforts on behalf of the Foundation during the current year. The Foundation has been adopted as the Auxiliary's major project, and, while it cannot be predicted accurately, it is safe to say that the activity of the Auxiliary committees is responsible for much of the activity taking place at the state level.

The Foundation's second annual report was published late due to the extremely heavy editing job that had to be done on the contributor lists. The 1952 report changed format in order to accommodate the large quantity of names which covered not only the contributors to the Foundation, but also the names of individual physicians who had made gifts directly to their medical schools during the year. It is believed that the current annual report contains, for the first time in history, a list of individual contributors to most of the nation's medical schools—30,300 individual members of the medical profession were listed as having made contributions directly to their medical schools. The report also listed 7,259 physicians and organizations who made contributions to the Foundation. The total number of individual physicians contributing to their medical schools and the Foundation amounted to approximately 17.5% of the total physician population in the United States.

The second annual meeting of A. M. E. F. chairmen was held in Chicago during the latter part of January and was attended by representatives from every state. At this meeting, the state chairmen heard the 1953 campaign outlined and participated in a panel discussion of mutual interest to all campaign committee members. The meeting afforded various state chairmen an opportunity to discuss their problems with each other and exchange ideas. The enthusiasm with which those attending participated prompted the directors to vote in favor of another meeting at the same time in 1954. The date for the 1954 annual meeting of chairmen has been established for Sunday, Jan. 24.

The Foundation has received letters from the deans of the 79 approved medical schools expressing their gratitude and appreciation for the financial assistance they have received as a result of contributions from the medical profession. Letters from college presidents and leaders in business, industry, and public life have been received in increasing numbers and offer congratulations to the medical profession for its efforts in behalf of the medical schools. These plaudits actually belong to members of the House of Delegates, trustees, and officers of the American Medical Association as well as the many working committees of the Foundation in every state. Without the wholehearted support of these and the many thousands of contributors, the funds would not have been available for distribution to the medical schools.

The remainder of the current year will be devoted to the conducting of intensive efforts to renew the support of those contributors who have not made their contribution in this calendar year. These efforts will consist of direct mail, both national and local, and personal solicitation on the part of state committees. In addition, considerable attention will be paid to those areas where weaknesses are evident.

Dr. Elmer L. Henderson, who served as the President of this Foundation since its inception in 1950 until his death on July 30, 1953, repeatedly sought the continued cooperation of the House of Delegates of the American Medical Association as well as of the leaders of state and local medical societies in an effort to further the aims and purposes of the Foundation. His efforts on behalf of those ideals and practices which have helped elevate the position of the medical profession in the eyes of the general public, are well-known, and his efforts on behalf of the medical schools in the United States were of equal intensity. Dr. Henderson firmly believed that the American system of medical education was capable of producing qualified physicians, and that in order to maintain that system it was necessary for every member of the profession to give of his time and money, or face the alternative of federal subsidy.

The Board of Directors feels that with the continued support of the American Medical Association and the state and county medical societies, the income of the Foundation can be increased to the desired level of 2 million dollars annually in the immediate future. It is on the belief that this cooperation and activity will continue, that the directors predicate their plans for the year ahead.

Appreciation

The directors of the American Medical Education Foundation wish to thank all those individuals and organizations, both lay and professional, who have so generously supported the foundation during the year. The first years of operation are decisive years in the Foundation's history, for the degree of continued support it receives will determine the degree of its current and future successes. Those who have given so freely of time, effort, and finances deserve the warmest possible recognition.

It is the desire of the directors to point up the continued generosity of the American Medical Association, its House of Delegates, trustees and officers for again making a half million dollar grant to the Foundation during the current year. The special allocation of operating funds which permits the Foundation to pass on every dollar raised to the medical schools deserves special acknowledgment and thanks; however, the $500,000 grant from the American Medical Association has been the cornerstone of this philanthropic effort and has established leadership necessary to attract ever-increasing numbers of contributors.

REPORT OF THE STUDENT AMERICAN MEDICAL ASSOCIATION

The Student American Medical Association during 1952 added further to its stature among organizations dedicated to advancement of the profession of medicine. Although only three years old, the Association now boasts strength and resources which command respect and consideration from all who maintain liaison with it. Although S. A. M. A.'s rapid growth and accompanying expansion of program contributed toward an unusual acceleration of activity, the addition of staff where needed, coupled with complete cooperation on the part of S. A. M. A.'s friends, helped the organization reach its highest and most effective peak to date.

Officers

The Association has continued its good fortune in securing qualified, capable leadership. Every area of the country continues to be represented on the Executive Council, and without exception these leaders have brought high credit to S. A. M. A. whenever and wherever they have served in an official capacity.

Due to the transition in moving the annual conventions from December to late spring the slate of officers which served throughout 1952 was, with wisdom, requested by the House of Delegates in December, 1952, to remain in office through the June, 1953, meeting. They were:

President: David Buchanan, University of Illinois College of Medicine.
Vice President: Clifford Vernick, Tufts College of Medicine.
Treasurer: Leland Hoar, University of Oregon Medical School.
Executive Secretary: Russell Staudacher, Chicago.
Executive Council:
Norman Henderson, Wayne University College of Medicine.
John Caskey, Baylor University College of Medicine.
John Morozumi, Stritch School of Medicine.
Joseph Mason, Boston University School of Medicine.
Charles McGaff, University of Louisville School of Medicine.
Frank Shubeck, University of Michigan Medical School.
Curtis Beam, University of Arkansas School of Medicine.

A new slate to serve through the convention in May, 1954, was elected in June. They are:

President: John H. Caskey, Baylor University College of Medicine.
Vice President: David J. La Fond, Marquette University School of Medicine.
Treasurer: Daniel D. Heffernan, Wayne University College of Medicine.
Executive Secretary: Russell Staudacher, Chicago.
Executive Council:
Clifford Vernick, Tufts College of Medicine.
Donald Harrop, University of Pennsylvania School of Medicine.
Patricia Stuff, Woman's Medical College of Pennsylvania.
Clifton Mountain, Boston University School of Medicine.
Leland Hoar, University of Oregon Medical School.
Stephen Plank, University of California School of Medicine.
Robert Crouch, Bowman Gray School of Medicine.

The following Senior Councilors served without vote and in an advisory capacity:

Ernest M. Irons, M.D., Past President, American Medical Association.
John McK. Mitchell, M.D., Dean, University of Pennsylvania School of Medicine.
Thomas P. Murdock, M.D., Trustee, American Medical Association.

Delegates to the American Medical Association

The following persons attended meetings of the House of Delegates of the American Medical Association as delegates from this Association:

June 1953: Joseph Mason, Boston University School of Medicine. Charles McGaff, University of Louisville School of Medicine.

December 1953: John Caskey, Baylor University College of Medicine. David La Fond, Marquette University Medical School.

Membership

Member chapters in S. A. M. A. today number 63 in as many medical schools. Increasing interest in becoming part of the national medical student voice and a personally directed campaign by Councilors in schools outside S. A. M. A. is expected to add at least 10 new chapters before the annual meeting in May.

Because of the diversity of factors contributing to the absence of chapters in certain areas, the Council is soliciting the help of members of the profession and particularly alumni of these nonchapter schools to assist in this project. Although several new chapters are in the process of organization, the following medical schools as yet are not affiliated: Stanford, Georgetown, George Washington, Howard, Johns Hopkins, Harvard, St. Louis, Washington, Columbia, Cornell, New York Medical, Rochester, South Carolina, Tennessee, Vanderbilt, Vermont, and Dartmouth.

Individual membership in the Association will exceed 19,000 by the year's end, with more than a score of chapters reporting 100% enrolment. This situation should continue as individual benefits of membership establish the desire to join S. A. M. A. as a freshman and continue affiliation through graduation.

As in the past, requests for information about the Association continue to come from groups and individuals at the premedical level. Every effort is made to acquaint these possible future members with S. A. M. A.'s aims and program.

Effective with the January, 1953, issue the Association's publication was available only to dues paid members, members-at-large, and honorary members. This policy provided the chapters with a most effective tool for membership promotion. American students in medical schools abroad, eligible as members-at-large, made application from more than a dozen foreign countries. The increase in the number of physicians applying as honorary members was especially gratifying, as it indicated a sincere interest on the part of physicians in their colleagues-to-be.

The Student Journal

By far its most important asset, the *Journal of the Student American Medical Association* continued to make its impact on the membership as well as those in the professional publishing world. Handicapped by an editorial staff of only two persons, the publication nonetheless survived the loss of assistant editors twice within a year to present a greatly improved format over its issues of a year ago. During 1953, the *Journal* added several departments in development of added usefulness for its student readers. These covered the areas of legal medicine, quackery, medicine in pictures, and the activities of the executive secretary's office.

In May, 1953, the *Journal* passed the break-even point in its existence and began to prove its value as a source of financial support for other Association activities. Today the publication produces a monthly surplus above expenses sufficient to foresee implementation of added member services.

With sincere thanks to the enthusiasm and cooperation of Mr. Thomas R. Gardiner and his capable staff, the advertising revenues have not only been maintained at a healthy level, but have increased.

Liaison

As S. A. M. A. spreads its sphere of influence to encompass the majority of medical students and medical schools it is asked to express itself on many questions of issue and importance. During 1953 S. A. M. A. succeeded in establishing new liaison with ancillary medical and student groups as well as strengthening those already established. The foremost achievement was the election of a S. A. M. A. representative to the Board of Directors of the National Intern Matching Program, which operates the mechanical matching plan for intern placement. To engender student support in this plan, the S. A. M. A. House of Delegates in June named a three-man auditing committee to inspect and report on the plan and its mechanics. This committee returned a highly commendatory report which was published in the *Journal.*

The Association continued its excellent rapport with the American Medical Association, the Association of American Medical Colleges, the American Academy of General Practice, the American Law Student Association, the National Association of Medical-Dental Bureaus, the Medical Exhibitors Association, and many others.

As the years pass, the Association sincerely hopes to effect working friendships with all associations and organizations engaged in a mutual advancement of the profession.

Annual Meetings

The 1953 meeting of the House of Delegates was held June 15, 16, and 17, at the Edgewater Beach Hotel in Chicago. More than 500 students and guests attended the three-day sessions, although the meeting dates were in conflict with exams. The convention program was outstanding and enthusiastically received, as were the various social functions. S. A. M. A.'s first technical exhibit drew more than 30 commercial and scientific exhibitors, who were well satisfied with this initial show exclusively for medical students.

The House of Delegates went on record in support of an earlier date for the 1954 meeting. Accordingly, it will be held May 1, 2, and 3, at the Sherman Hotel, Chicago.

Award

The Association was pleased to accept an attractive illuminated plaque as an award from the American Heritage Foundation for S. A. M. A.'s support of the National Non-Partisan Register and Vote Campaign in 1952.

Finances

The financial picture of the Association improved during 1953 to the extent that it repaid the American Medical Association $10,000 as partial repayment of obligations assumed during the organization's first three years. It is planned that all remaining obligations will be repaid in the near future, leaving S. A. M. A. solvent and successful.

In Appreciation

The Student American Medical Association is sincerely aware of the role played by its friends in American medicine to help the organization move ahead. It also is cognizant of the fact that without this cooperation the Association would enjoy only a part of the success it now does. The Association is also indebted to those corporations and individuals who participated in S. A. M. A.'s progress through advertising in its *Journal* and exhibiting at the convention. Special thanks are due the American Medical Association, Abbott Laboratories, the Blue Shield Medical Care Plans and the Bureau of Exhibits of the American Medical Association for courtesies extended on the occasion of the 1953 convention.

Without the generous help and support of the American Medical Association, this Association could never be where it is today. Therefore, humble appreciation is given for the gift of personnel and headquarters space for S. A. M. A.'s administrative operations. Individual thanks are due everyone from the House of Delegates and Board of Trustees down to the kindly folks who maintain S. A. M. A.'s offices and headquarters facilities. To Dr. Lull, Secretary and General Manager, and Dr. Howard, Assistant Secretary, go personal thanks for counsel and guidance given the executive secretary as he undertook directions of S. A. M. A.'s activities.

This report would be most incomplete without mention of the state and county medical societies and their executive leaders for their strong, never-ending support of S. A. M. A.'s program at both local and national levels. The medical school deans also earned the praise and respect of S. A. M. A. for the way in which they helped make the organization move forward on their campuses.

The Association also wishes to make record of the contributions made by the behind-the-scenes workers in the executive offices without whom the program would be forever slowed.

Respectfully submitted,

John Caskey, President.
David LaFond, Vice-President.
Daniel Heffernan, Treasurer.
Russell Staudacher, Executive Secretary.

BIG PENSIONS AND BIG GOVERNMENT

Resolutions reaffirming the actions of the House of Delegates in June, 1949,[1] opposing congressional action to force physicians under the Old-Age and Survivors Insurance section of the Social Security Act will be introduced at the meeting of the House of Delegates in St. Louis, Dec. 1-4. The American Dental Association reaffirmed its opposition in September. Somewhat similar views have been expressed in recent years by the governing bodies of the American Bar Association, the American Farm Bureau Federation, and other national organizations composed largely of self-employed persons. Recently the American Institute of Accountants changed its position from one of opposition to neutrality.

Most employed persons, including many members of these organizations, are now covered by the Social Security Act. The Chairman of the Committee on Legislation of the American Medical Association and the Association's Economist and Director of the Bureau of Medical Economic Research have prepared jointly an analysis (page 921) of the outstanding defects of Old-Age and Survivors Insurance (OASI). They have set forth some of the basic reasons why members of the medical profession should continue to oppose the proposed extension of the Social Security Act to cover self-employed physicians and others not covered by previous legislation. The Director of the Bureau, speaking for himself but not necessarily for the A. M. A., has suggested three fundamental reforms that would convert the plan into a reasonably equitable system. Numerous bills pertaining to social security now before Congress and statements during the year by President Eisenhower, at the behest of his advisors, make it reasonable to expect that the House of Delegates will take cognizance of these new developments on this highly controversial issue.

An ostensible reason for physicians to disapprove compulsory coverage under OASI warrants only a brief comment. The median age at which self-employed physicians over age 64 are currently retiring is 74. The retirement ages of self-employed lawyers, dentists, and farmers is probably about the same. Under the so-called work rule no eligible person can draw an OASI pension if he earns $75 a month between ages 65 and 75. This would obviously mean that half of the self-employed physicians would, under the President's proposal, be required to pay social security taxes but would not receive one penny of benefits until age 74. But relaxing the "work rule" to make coverage more attractive to these 10 million gainfully employed would, unless accompanied by a sharp increase in OASI taxes, merely increase the get-something-for-next-to-nothing potential of this act. The President's proposal would bring us close to Townsendism, and an elimination of the "work rule" would just about fulfill the hopes and dreams of Dr. Francis E. Townsend.

The basic objection to bringing an additional 10 million persons under OASI is that such an action by the Congress would be another long step toward Big Government and the Welfare State. Social security taxes, counting both employers' and employees', are currently only token payments and will defray only a portion of the costs of the OASI pensions. The tax rates of employers and employees could be doubled and also graduated according to age—a change that is much more urgent than a modification of the "work rule." Yet on May 20 the Congress was asked to take the steps necessary to prevent the scheduled increase of one-half of one per cent in the tax rate, which, according to present law, will begin on January 1, 1954. The unpaid balance of the pension costs as older persons receive their monthly pension checks must be paid by another generation. Those who oppose this steady march toward the Welfare State must always refuse the bait: in this case, pensions at cut-rate prices. They must oppose the doctrine of individual irresponsibility except for the care of those in dire need, which, in fact, is the essence of the principles that guide the life of a physician in his practice. They must always stand firmly against the exploitation of youth by those who were born many years earlier. They must insist on standing on their own feet and providing for their own retirement needs. Those who can pay should pay their own way; those who cannot pay must, of course, be helped.

Opposition to this trend toward the Welfare State is one reason for supporting the Jenkins-(Reed)-Keogh bills (H. R. 10 and 11), which would establish a voluntary retirement plan for the self-employed and the pensionless employed. They would amend the federal internal revenue code but would not change the Social Security Act. They are in the public interest. The amount of each person's pension would be determined by how much he set aside for old age, and not one penny would be added to his fund by the government. He would be permitted to defer taxes on the annual amount set aside each year until he retired and began to receive his pension, which would be currently taxable. The provisions in these bills for tax deferment until retirement are the counterpart of those now enjoyed by employed persons covered by more than 20,000 tax-exempt pension plans. Except in case of permanent disability he could not draw benefits from his fund until age 65, but after age 65 he could draw out benefits as he sees fit. These bills, unlike the Social Security Act, would not force one into idle retirement in order to draw on his own pension fund. He could keep right on working as the majority of practicing physicians do.

VITAMIN B_{12} RESEARCH

About 60 scientists representing government, university, hospital, and industrial laboratories recently met in Baltimore to participate in a symposium on current research in vitamin B_{12}. The program, which was organized by Dr. Bacon F. Chow, associate professor of biochemistry in the School of Hygiene and Public Health of Johns Hopkins University, included reports on the metabolic roles of vitamin B_{12}, the mechanism of its action in blood formation, and related subjects. During the two day conference, 20 investigators presented summaries of their data and conclusions on the various facets of the problems.

Evidence was presented that indicates an important role of the vitamin in the synthesis of nucleic acids and in the formation or function of such metabolically active compounds as glycine, serine, methionine, and choline. Interrelationships between vitamin B_{12} and other vitamins, such as pyridoxine and pantothenic acid, were demonstrated. Additional evidence for the interdependence of vitamin B_{12} and the folic acid series was presented and the role of intrinsic factor was reviewed. Growth studies were reported emphasizing the importance of adequate supplies of the vitamin in the metabolism of carbohydrate and fat, including not only the conversion of carbohydrates to fat but the metabolism of fat itself.

Vitamin B_{12} has been shown to play an important role in modifying the concentration of sulfhydryl-containing components of physiological importance, among which might be enumerated glutathione and coenzyme A. The hypothesis was presented that in the absence of adequate supplies of the vitamin, coenzyme A would not be reduced from the disulfide to the sulfhydryl form and would, therefore, inhibit the normal pathways of fat metabolism. Under conditions of chronic deprivation of vitamin B_{12}, evidence in support of this thesis is found in the accumulation of fat in the tissues of both chicks and rats. Much detailed study of isolated enzyme systems will be required for a fuller understanding of these highly suggestive leads.

Of clinical importance were the reports on anemia and intrinsic factor studies. Additional evidence of the essentiality of both vitamin B_{12} and the folic acid group in blood formation was presented. The current concept that pernicious anemia represents a tissue deficiency of vitamin B_{12} produced by hypofunction of intrinsic factor-producing cells in the gastrointestinal tract, which in turn results in failure of absorption of dietary vitamin B_{12}, was reemphasized. Mechanisms of action of intrinsic factor were discussed. Reports suggesting a wide variation in the amount of intrinsic factor present in patients with pernicious anemia and possibly in the aged, although preliminary in nature, emphasized the need for caution on the part of the physician in the oral use of intrinsic factor-vitamin B_{12} preparations in the treatment of pernicious anemia. Such preparations when administered in adequate quantities are effective. This presupposes adequate stability and proper standardization of the preparation. It is possible to administer inadequate doses to certain patients, particularly to those in whom production of natural intrinsic factor is virtually nil. The neurological manifestations of pernicious anemia may be masked by the concomitant administration of folic acid and inadequate doses of vitaman B_{12}-intrinsic factor combinations. This emphasizes the need on the part of the physician for close and constant observation of the pernicious anemia patient treated by the oral route.

A highlight of the symposium was the report of a clinical group from Johns Hopkins Hospital. All of 20 patients with pernicious anemia treated for a period of three and one-half years or longer have responded and have been maintained satisfactorily and completely with large oral doses of vitamin B_{12} administered without intrinsic factor. A single initial oral dose of 5 mg. was adequate in every instance to produce a satisfactory response for patients in relapse. After this, a single oral dose of 1 mg. administered once a week has maintained these patients in remission. No neurological or hematological relapse has been observed, and periodic blood studies revealed completely satisfactory maintenance of the blood picture. It was emphasized that smaller oral doses administered at more frequent intervals, although effective in certain patients, failed to produce a satisfactory response in all patients. The clinicians warned that this study must be continued for a longer period, because of the vagaries of pernicious anemia, before this method of treatment could be considered as a substitute for parenterally administered vitamin B_{12}.

In another series of reports at the symposium, vascular complications of diabetes mellitus, such as diabetic retinitis and the intraglomerular capillary sclerosis of the Kimmelsteil-Wilson syndrome, were discussed. Literature and case record research were reported to have revealed that the incidence of retinitis apparently increases with the duration of the disease and is present in a very large percentage of patients with a history of diabetes mellitus of 20 years or longer. A correlation with the incidence of diabetic neuritis, the symptoms of which in some respects resemble the neuritic involvement of pernicious anemia, was also suggested.

In relation to these findings was the discovery of investigators from the Johns Hopkins group that *patients* with diabetic retinitis excreted more of a test dose of vitamin B_{12} than did diabetics without retinitis or normal persons. Normal subjects excrete an average of about 9 mcg. of vitamin B_{12} in an eight hour period after injection of a test dose of 50 mcg. of vitamin B_{12}. Diabetics without retinitis excrete an average of 4.2 mcg. and those with retinitis, 19 mcg. Studies of collaborating groups indicate that abnormally high amounts of an adrenal cortical substance are excreted in the urine of patients with diabetic retinitis and that those without retinitis excrete normal or lower than normal amounts of this substance.

The reports presented at this symposium indicate that research in the fundamental roles of vitamin B_{12} have materially extended the concept of its importance in basic metabolism. Interesting and promising new channels for research were demonstrated. Of particular importance was the development of improved techniques, such as the use of radioactive-cobalt-labeled vitamin B_{12}. This symposium emphasizes the value and need for collaboration on the part of observers and groups active in different fields of research.

ORGANIZATION SECTION

SCIENTIFIC EXHIBIT—SAN FRANCISCO MEETING

The Scientific Exhibit will again be one of the features of the Annual Meeting in San Francisco, June 21-25, 1954, with exhibits portraying advances in all branches of medicine. The exhibits will be grouped as far as possible according to the different specialties, but their scope will be broad, intended for general interest rather than for the specialist. Representatives to the Scientific Exhibit have been elected by each Section of the Scientific Assembly to assist and advise the committee in the procurement and selection of exhibits as follows:

Section on Anesthesiology, Scott M. Smith, M.D., 910 Medical Arts Bldg., Salt Lake City 1.

Section on Dermatology and Syphilology, Samuel M. Bluefarb, M.D., 30 N. Michigan Ave., Chicago 2.

Section on Diseases of the Chest, Edwin R. Levine, M.D., 109 N. Wabash Ave., Chicago 2.

Section on Experimental Medicine and Therapeutics, Joseph F. Ross, M.D., Evans Memorial Hospital, 65 E. Newton St., Boston 18.

Section on Gastroenterology and Proctology, J. P. Nesselrod, M.D., 636 Church St., Evanston, Ill., and William H. Dearing Jr., M.D., Mayo Clinic, Rochester, Minn.

Section on General Practice, Charles E. McArthur, M.D., 1934 E. Fourth Ave., Olympia, Wash.

Section on Internal Medicine, John S. Lawrence, M.D., 405 Hilgard Ave., Los Angeles 24.

Section on Laryngology, Otology and Rhinology, Walter E. Heck, M.D., Stanford University Hospital, Clay and Webster St., San Francisco 15.

Section on Military Medicine, Brig. Gen. Rawley E. Chambers, MC, Chief, Professional Division, Office of the Surgeon General, Department of the Army, Room 2837, Main Navy Bldg., Washington 25, D. C.

Section on Nervous and Mental Diseases, G. Wilse Robinson Jr., M.D., 2625 The Paseo, Kansas City 8, Mo.

Section on Obstetrics and Gynecology, Frederick H. Falls, M.D., University of Illinois College of Medicine, 1853 W. Polk St., Chicago 12.

Section on Ophthalmology, W. F. Hughes Jr., M.D., 1853 W. Polk St., Chicago 12.

Section on Orthopedic Surgery, J. Vernon Luck, M.D., 1930 Wilshire Blvd., Los Angeles 5.

Section on Pathology and Physiology, Frank B. Queen, M.D., 3181 S. W. Sam Jackson Park, Portland 1, Ore.

Section on Pediatrics, F. Thomas Mitchell, M.D., LeBonheur Children's Hospital, 848 Adams, Memphis 5, Tenn.

Section on Physical Medicine and Rehabilitation, Donald A. Covalt, M.D., 400 East 34th St., New York 16.

Section on Preventive and Industrial Medicine and Public Health, Paul A. Davis, M.D., 633 E. Market St., Akron 4, Ohio.

Section on Radiology, Richard H. Chamberlain, M.D., 3400 Spruce St., Philadelphia 4.

Section on Surgery, General and Abdominal, John H. Mulholland, M.D., 477 First Ave., New York 16.

Section on Urology, Roger W. Barnes, M.D., Chairman, 1216 Wilshire Blvd., Los Angeles 17; Norris J. Heckel, M.D., 122 S. Michigan Ave., Chicago 3; and George H. Ewell, M.D., 16 S. Henry St., Madison 3, Wis.

Application blanks for space in the Scientific Exhibit at the San Francisco Meeting are now available. They may be obtained from the above Section Representatives or from the Director, Scientific Exhibit, American Medical Association, 535 N. Dearborn St., Chicago 10, Ill.

NEW A. M. A. PUBLICATIONS

Medical Society Grievance Committees

This pamphlet, prepared by the Council on Medical Service of the American Medical Association, shows the organization and operation of local grievance committees. The data have been compiled from reports submitted to the Council by 198 county medical societies representing a variety of urban and rural committees.

Activities of County Medical Societies

This pamphlet, just off the press, is the report of another year's survey of the activities of county medical societies and contains tables and comments concerning data prepared primarily for use by medical society offices. The completeness of this report was made possible through the cooperation of the officers of 927 medical societies. The Council, since 1948, has maintained an ever-increasing file of data and information concerning such activities.

Rule Book of Committee on Cosmetics

Just off the press is the revised edition of the "Offiical Rules of the Committee on Cosmetics of the A. M. A." This booklet contains requirements for presentation of products and rules governing the acceptance of products by the Committee. Copies are available on request.

Proceedings of Conference on Cancer

The Proceedings of the Second Conference on Steroids and Cancer, held in April, 1951, have now been published and are available in a paper-bound volume at $3.50 from the Order Department, American Medical Association, 535 North Dearborn Street, Chicago 10, Ill.

WMA TO MEET IN ROME NEXT YEAR

The World Medical Association will hold its 1954 meeting in Rome, Sept. 26-Oct. 2. Since 1954 is a Holy Year, there will be heavy demands for transportation and hotel reservations. Any A. M. A. member who wishes to attend this meeting should write to the World Medical Association, 345 East 46th Street, New York 17, as soon as possible. The WMA will secure transportation, hotel reservations, and help plan any side tours of Europe that the member desires. No charge is made to the physician for this service.

REGIONAL CONFERENCES ON VETERANS MEDICAL CARE

The Committee on Federal Medical Services of the A. M. A. Council on Medical Service is sponsoring a series of regional conferences throughout the United States to discuss A. M. A. policy regarding medical care for veterans with non-service-connected disabilities. For the present, one-day meetings have been scheduled for Dallas, Atlanta, New York, and Washington, and representatives from five surrounding states have been invited to each. Following are the dates and the states to be represented at each session: Dallas, Friday, Nov. 6—Texas, Louisiana, Oklahoma, Arkansas, and Mississippi; Atlanta, Sunday, Nov. 8—Tennessee, Alabama, Georgia, South Carolina, and Florida; New York, Friday, Nov. 13—New York, Pennsylvania, New Jersey, Connecticut, and Rhode Island; and Washington, Sunday, Nov. 15—Maryland, Virginia, West Virginia, Delaware, and North Carolina.

PR CONFERENCE LUNCHEON

The luncheon speaker at the American Medical Association's Public Relations Conference in St. Louis Nov. 30 will be Dr. Leo H. Bartemeier, Detroit, Chairman of the A. M. A.'s Committee on Mental Health. Dr. Bartemeier will discuss "What Motivates the Public's Attitude Toward Medicine?"

MEDICAL NEWS

CALIFORNIA

Psychiatric Meeting.—The Southern California Psychiatric Society will hold its first annual meeting Nov. 14 at the Hotel Statler, Los Angeles. The following program will be presented at 1 p. m.:

- Albert J. Glass, Col. (MC), Ft. Sam Houston, Texas, Psychotherapy in the Combat Zone, (discussant, Ralph R. Greenson, Beverly Hills).
- Milton H. Erickson, Phoenix, Ariz., Development of an Acute Limited Obsessional Hysterical State in a Normal Hypnotic Subject, (discussant, Judd Marmor, Beverly Hills).
- Douglass W. Orr, Seattle, Common Pitfalls in Psychotherapy, (discussant, Leo Rangell, Beverly Hills).

A cocktail party, 6 p. m., will precede the dinner dance in the Golden State Room.

COLORADO

Rural Health Conference in Denver.—A regional Rural Health Conference will be sponsored by the Colorado State Medical Society at the Shirley-Savoy Hotel, Denver, Nov. 11-12. The address of welcome by Dr. Claude D. Bonham, Boulder, president of the state society, Wednesday, 9:45 a. m., will be followed by a panel discussion of the medical budget. At 12:15 p. m. Wednesday and Thursday, there will be a luncheon and round-table discussion of rural health problems led by guest speakers, Mr. Aubrey D. Gates, Little Rock, Ark., Field Director, A. M. A. Council on Rural Health, and Dr. Fred A. Humphrey, Fort Collins, Council member. Opening the Thursday session, 9 a. m., will be "A Typical County Health Survey—Its Objectives and Results" with discussion by Dr. Murland F. Rigby, Rexburg, Idaho, and Dr. Valentin E. Wolhauer, Brush. The sessions will conclude with the discussion, "The Use and Abuse of the Country Doctor," by Mrs. Alonzo A. Petteys, editor, *Daily High Plains Journal,* Sterling, and Tee Simms, ranch home editor, *Record-Stockman,* Denver.

CONNECTICUT

Lectures on Cardiovascular Disease.—The Stamford Heart Association announces its second monthly series of lectures on cardiovascular disease for physicians in Fairfield County, beginning Nov. 10. Topics and speakers include:

- Arteriosclerosis, David P. Barr, New York.
- Diagnostic Technique in Cardiovascular Disease, Arthur Grishman, New York.
- Surgical Treatment of Cardiovascular Disease, Reginald H. Smithwick, Boston.
- Rheumatic Fever, Gene H. Stollerman, New York.
- Problems in Diagnostic Analysis and Treatment of Dyspnea, Dickinson W. Richards, New York.
- Care of the Patient after Myocardial Infarction, William Dock, Brooklyn.
- Heart Disease and Pregnancy, Burton E. Hamilton, Brookline, Mass.

There is no fee for the series, which is accredited and endorsed by the Academy of General Practice and the Stamford Medical Society. For information contact Mrs. Shirley K. Sarkin, Executive Secretary, Stamford Heart Association, Stamford Hospital, Stamford.

ILLINOIS

Personal.—Dr. Clara Edmunds Holmberg, Springfield, was honored at a recent meeting of the Sangamon County Medical Society when she was presented with a 50 year club certificate and pin from the Illinois State Medical Society.

Chicago

Cardiac Conference.—The cardiovascular committee of the Cook County Hospital announces that the next regular monthly clinicopathologic cardiac conference will be held Nov. 13, 11 a. m. to 12 noon in the Children's Amphitheatre, 700 S. Wood St. "Studies on the Pharmacology and Clinical Use of Quinidine in Heart Disease" will be presented by Dr. George C. Sutton, Evanston, with discussion by Drs. Chauncey C. Maher and Louis Feldman, Chicago.

Society News.—The Chicago Medical Society announces a dinner, 6:30 p. m. Nov. 12, at the Sheraton Hotel, 505 N. Michigan Ave., in honor of Dr. Armand J. Quick, professor of biochemistry, Marquette University School of Medicine, Milwaukee, and Dr. Joseph F. Ross, associate professor of medicine, Boston University School of Medicine, who will be guest speakers at the joint meeting of the Chicago Medical Society and the postgraduate course in cardiology and hematology, which will follow the dinner. At 8 p. m. Dr. Quick will discuss "The Basic Factors in Hemostasis." Dr. Ross will present "The Blood Volume in Congestive Heart Failure."

Fund for Muscular Dystrophy Research.—The Chicago chapter of the Muscular Dystrophy Associations of America announces a program to assist in raising funds for the support of medical research in some 16 universities throughout the United States. The chapter will have available during November, the month of the national drive, and December speakers, educational films, and other free material for any organization requesting them. (Contact Lee Kling, AMbassador 2-7095, or write to Muscular Dystrophy Association, Box 455, Chicago.) The annual dance of the Chicago chapter will be held Nov. 14 at the U. E. Hall, 37 S. Ashland Ave. The Chicago Medical Advisory Board is composed of Drs. Louis Scheman and Ralph H. Kunstadter.

Phi Delta Epsilon Lectures on Radioisotopes.—The chapters of Phi Delta Epsilon fraternity of three medical schools in Chicago are sponsoring their annual lectureship Nov. 10-12 in honor of Dr. Isaac A. Abt, professor emeritus of pediatrics, Northwestern University Medical School; Dr. Julius H. Hess, professor emeritus of pediatrics, University of Illinois College of Medicine; and Dr. John J. Sheinin, president, Chicago Medical School. The lecturer, Paul C. Aebersold, Ph.D., director of isotope research, Atomic Energy Commission, Oak Ridge, Tenn., will speak on the following subjects:

- Nov. 10, 4 p. m. (Thorne Hall, Northwestern University Medical School), Contributions of Atomic Energy to Medicine.
- Nov. 11, 1 p. m. (University of Illinois Medical School), Radioisotopes—Tools for Medicine.
- Nov. 12, 8 p. m. (Chicago Medical School—Kling Auditorium, Mt. Sinai Hospital), Use of Radioisotopes in Medical Research, Diagnosis, and Therapy.

On Tuesday a dinner will be given in honor of the lecturer and Drs. Abt, Hess, and Sheinin.

NEW JERSEY

Lecture on Expert Testimony.—Dr. Winfred Overholser, professor of psychiatry, George Washington University School of Medicine, Washington, D. C., will give the 7th annual C. C. Beling memorial lecture, "Medical Expert Testimony and Its Improvement," under the auspices of the New Jersey Neuropsychiatric Association at the Academy of Medicine of Northern New Jersey, 91 Lincoln Park, Newark, Nov. 11, 8:45 p. m.

NEW YORK

Society News.—At the meeting of the Rochester Academy of Medicine (1441 East Avenue), Nov. 10, 8:30 p. m., Dr. Wilfred G. Bigelow, Toronto, Canada, will speak on hypothermia. The Dec. 1 meeting will be addressed by Dr. George Hoyt Whipple, Rochester, who will discuss "Blood Proteins—Hemoglobin and Plasma."

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Discussion of Cardiovascular Surgery.—Dr. Marcus M. Ravitch, director of surgery, Mount Sinai Hospital, New York City, will discuss "Surgical Treatment of Cardiovascular Disorders," Nov. 12, 8:30 p. m., in the auditorium, Freeman Pavilion, Jewish Sanitarium and Hospital for Chronic Diseases, 86 East 49th St., Brooklyn 3.

Hospital News.—At the staff conference of High Point Hospital, Port Chester, Nov. 11, 8:30 p. m., at the New York Academy of Sciences, 2 E. 63d St., New York City, the topic will be "Psychoanalysis of Groups" and the speaker, Dr. Alexander Wolf, New York. All members of the profession are invited to attend.

Cancer Teaching Day.—The Dutchess County Medical Society will observe its cancer teaching day, Nov. 11, with an afternoon meeting at Sadlier Hall, St. Francis Hospital, Poughkeepsie, and an evening meeting at Ryan Hall, Hudson River State Hospital in Poughkeepsie. After a tour of the radioisotope laboratory, the following program on the early diagnosis of cancer will be presented by New York City physicians: breast, Dr. Jerome A. Urban; stomach, Dr. George T. Pack; cervix, Dr. James A. Corscaden; and lung, Dr. Laurence Miscall. A social hour, 6 p. m., will precede dinner, which will be followed by a business meeting at 8 p. m. Advance reservations for dinner are required. Checks for $4 should be sent to Dr. Reuben T. Lapidus, 39 Hooker Ave., Poughkeepsie.

Conference on Aging.—The second annual Capital District Conference on Aging will be sponsored by the Albany County Department of Public Welfare at the Ann Lee Home, Albany, Nov. 12, 1-4 p. m., for discussion of "Rehabilitation of Older People." Dr. John J. Phelan, medical director, Ann Lee Home, will serve as moderator at 2:05 p. m. The first panel, "Medical Aspects of Rehabilitation," 2:15 p. m., will include discussions on (1) food, (2) cardiac rehabilitation (Dr. Raymond Harris, Albany), and (3) psychologic and psychiatric problems (Dr. Eugene Davidoff, Schenectady). Participating in the general discussion will be Drs. Philip L. Forster, John W. Ghormley, Thomas J. O'Donnell, Marcus B. Einhorn, and William E. Pickett, Albany, Harold E. Marden, Delmar, and William Griesau, Troy. A panel, "Vocational Rehabilitation Employment Problem of the Aging," at 2:15 p. m., will be followed by general discussion.

OHIO

Lecture on Lung Lesions.—The Fort Steuben Academy of Medicine is presenting a monthly series of lectures at the Fort Steuben Hotel, Steubenville, to which physicians and interns are cordially invited. On Nov. 10 Dr. Eugene P. Pendergrass, Philadelphia, will present "Roentgen Diagnosis of Legions of the Lung."

Diabetes Detection Program.—The Cleveland Diabetes Society and the Diabetes League of Greater Cleveland in cooperation with the American Diabetic Association and the Cleveland City Health Department will conduct a mass screening program for diabetes detection, Nov. 15-21. The cooperation of all members of the medical profession and allied professions is requested.

Society News.—The Academy of Medicine of Cincinnati will have as guest speaker on Nov. 10 Dr. Earl D. Osborne, professor of dermatology and syphilology, University of Buffalo School of Medicine, who will address the joint meeting with the Cancer Council on the treatment of skin cancers. On Nov. 24 Dr. John C. Burch, professor of obstetrics and gynecology, Vanderbilt University School of Medicine, Nashville, Tenn., will discuss "The Management of Leukorrhea."

UTAH

Course on Physiological Basis for Present Day Therapy.—The American College of Physicians will sponsor a course on present-day therapy and its physiological basis at the department of medicine, University of Utah College of Medicine, Salt Lake City, Nov. 9-13, under the direction of Drs. Maxwell M. Wintrobe and Louis S. Goodman. The guest faculty includes Dr. J. Burns Amberson and Alfred Gilman, Ph.D., New York, and Dr. Harry Eagle, Bethesda, Md. Fourteen members of the University of Utah faculty will participate with the guests in symposiums on (1) pulmonary emphysema and its complications, (2) disseminated lupus erythematosus, and (3) therapeutic uses of corticotropin (ACTH) and cortisone. On Monday there will be round tables on splenic disorders and hematology. Monday, 8 p. m., Dr. Amberson will give the Tyndale lecture, "Aspects of Chemotherapy of Tuberculosis." Staff rounds will be made Wednesday morning, and a tour of laboratories, the university, and the city is scheduled for the afternoon. In the evening Dr. Eagle will have as his topic, "Studies in Mode of Action of Antibiotics." Thursday afternoon there will be a round-table discussion on therapeutic indications, and Thursday evening Dr. Gilman will talk on the acidification of the urine. A roundtable on diuretics will be held Friday morning.

WEST VIRGINIA

Practitioners Meet in Parkersburg.—The West Virginia chapter of the American Academy of General Practice will hold a scientific meeting at the Chancellor Hotel in Parkersburg, Nov. 8, 10:30 a. m. to 3:30 p. m. The following program has been arranged by Dr. Seigle W. Parks, Fairmont, chairman of the program committee:

Pyelitis in Pregnancy, George Nordlinger, associate clinical professor of obstetrics and gynecology, George Washington University School of Medicine, Washington, D. C.

Toxemia in Pregnancy and Abortion, George J. Fuchs Jr., chief medical officer, department of obstetrics and gynecology, District of Columbia General Hospital, Washington, D. C.

GENERAL

Meeting on Rheumatism.—The Ohio and Western Pennsylvania regional meeting, American Rheumatism Association, will convene at the Mayflower Hotel, Akron, Ohio, Nov. 11. Presentations will be made by Drs. Robert M. Stecher, Cleveland; Currier McEwen, Charles A. Ragan, Richard H. Freyberg, and Robert L. Preston, New York; John H. Talbott, Buffalo; Gordon M. Martin, Rochester, Minn.; and Joseph J. Bunim, Bethesda, Md. At 3:40 p. m. there will be a period of panel questions and answers, and at 7 p. m. a dinner. Registration fee, $5; dinner tickets, $5.

Papers Invited for Clinical Research Meeting.—The Northwest Society for Clinical Research will hold its annual meeting in combination with the western section of the American Federation for Clinical Research, Jan. 28, 1954, in Portland, Ore. The society will also meet with the Western Society for Clinical Research, Jan. 29-30. Members desiring to present papers will have space on the western section program. Abstracts should be sent in triplicate, before Nov. 15, to Dr. Isidore Edelman, Secretary, University of California, Medical Office, San Francisco Hospital, Potrero and 22nd streets, San Francisco.

Society for Crippled Children and Adults.—The annual convention of the National Society for Crippled Children and Adults will be held at the Palmer House, Chicago, Nov. 11-14, under the presidency of William T. Sanger, Ph.D., Richmond, Va., who will deliver the presidential address at 9:30 a. m. Thursday. His remarks will be followed by the talk, "A World Without Limits," by Dr. Edward J. McCormick, Toledo, Ohio, President of the American Medical Association, who is councilor for the society. The Friday session will be opened at 9 a. m. by a presentation, "Rehabilitation—Key to Human Dignity," by Dr. Henry H. Kessler, Newark, N. J. At a parents' institute to be held Friday afternoon, Frances R. Horwich, Ph.D., who presents the TV program, "Ding Dong School," will give a talk, "Understanding Your Child." Dr. Julius B. Richmond, professor of pediatrics, State University of New York College of Medicine at Syracuse, will participate in a panel, "Self Understanding for Parents of Handicapped Children." The president's dinner will be held at 7:30 p. m. in the grand ballroom. Saturday, 9:30 a. m. a seminar for physicians, therapists, nurses, social workers, etc., will be held in Room 14, where Dr. Kessler will speak on rehabilitation techniques.

Neurological Surgeons Meet in New Orleans.—The Congress of Neurological Surgeons will convene at the Hotel Roosevelt in New Orleans, Nov. 12-14. A panel discussion on the anatomy and physiology of the frontal lobes is scheduled for Thursday, 2-4 p. m., and a panel discussion, "Psychosurgery: Indications and Sequelae," for Friday, 9-11 a. m. Saturday morning there will be a panel on the use of fluids and electrolytes in the management of the neurosurgical patient. Sir Geoffrey Jefferson, emeritus professor of neurosurgery and lately director of the neurosurgical laboratories, University of Manchester, England, will speak on (1) chiasmal gliomas, (2) trigeminal tumors, benign and malignant, and (3) changing ideas on the integration of the brain. Other guest speakers include: Dr. A. Earl Walker, Baltimore; Dr. Robert G. Heath, Hymen S. Mayerson, Ph.D., Dr. Alton Ochsner, and Walter Wilde, Ph.D., New Orleans; Dr. Stanley Cobb, Boston; Dr. Gerhardt Von Bonin, Chicago; Dr. Harold Himwich, Galesburg, Ill.; and Dr. J. Lawrence Pool, New York. A cocktail party, 6:30-8 p. m. will precede the banquet and dance (informal dress) on Friday. The congress will be preceded by a review course in neuroradiology under the direction of Dr. Joseph N. Ané, New Orleans, Nov. 11, for which Dr. Harold O. Peterson, Minneapolis, will be guest radiologist.

Joint Meeting on Tropical Medicine and Hygiene.—The annual meeting of the American Society of Tropical Medicine and Hygiene will be held jointly with the 20th annual meeting of the American Academy of Tropical Medicine at the Brown Hotel, Louisville, Nov. 12-14. The academy will sponsor a symposium, entitled "Global Interest in Tropical Medicine," and the society, a symposium on "Diarrheal Diseases Other Than Amebiasis." On Thursday, 9 a. m., the 18th Charles Franklin Craig lecture, "Problems in the Control of Schistosomiasis," will be presented by Dr. Henry E. Meleney, Louisiana State University School of Medicine, New Orleans. Thursday, 7 p. m., the American Society of Tropical Medicine and Hygiene will hold a dinner in celebration of the 50th anniversary of its founding, with Dr. Lewis W. Hackett, New York, presiding. Friday afternoon there will be a tour of the University of Louisville Medical School to which all registrants are invited. The joint dinner session of the society and the academy is scheduled for Friday, 7 p. m. Dr. Albert B. Sabin, Cincinnati, will preside. Dr. William A. Sodeman, Columbia, Mo., will deliver the presidential address of the society, "Our Future?" The presidential address of the academy, "Unfinished Business in Tropical Medicine," will be delivered by Dr. Meleney.

School Health Association Meets in New York.—The annual meeting of the American School Health Association will be held Nov. 8-13 at the Hotel New Yorker in New York, joint sessions with sections of the American Public Health Association being scheduled Tuesday to Friday. Dr. Guy N. Magness, University City, Mo., president, will present his report Monday, 11 a. m., immediately after a talk, entitled "Tuberculosis Case Finding in Schools," by Dr. William E. Ayling, Syracuse. Participating in the Monday afternoon program will be Dr. Edmund P. Fowler, New York, who will discuss "Conservation of Hearing in Schools" and Dr. Helen C. Newman, Chicago, who will speak on mental hygiene in the classroom. Monday, 8:30 p. m., Dr. Carl C. Fischer, Philadelphia, will address the school health services section on the role of the Advisory Health Council in the school health program, and Dr. Donald A. Dukelow, Chicago, and Fred V. Hein, Ph.D., A. M. A. consultants in school health, will give the "Preliminary Report of the Fourth National Conference on Physicians in Schools." The annual banquet will be held Thursday at 6:30 p. m. in the north ballroom, where the William A. Howe award will be bestowed on Dr. Charles C. Wilson, professor of education and public health, Yale University, New Haven, Conn., and greetings from the American Public Health Association will be presented by its executive secretary, Dr. Reginald M. Atwater, New York.

College of Cardiology Meets in Cleveland.—The fall meeting of the American College of Cardiology will be held at the Hotel Statler, Cleveland, Nov. 6-7. The speakers and their topics will be:

Philogenesis and Ontogenesis of Congenital Malformations of the Heart, Maurice Lev, Miami Beach, Fla.
Embryological Development of the Heart and Congenital Abnormalities of the Heart (two motion pictures); Cyanosis in Congenital Heart Disease (motion picture), Robert F. Rushmer, Seattle.
Hereditary Aspects of Congenital Heart Disease, Frank R. Hanrahan and Henry A. Zimmerman, Cleveland.
Life Expectancy of Congenital Heart Disease, Richard S. Gubner, Brooklyn.
Incidence of Congenital Cardiac Malformations, Sidney E. Blumenthal, New York.
Congenital Cardiac Anomalies Associated with Mongolism, Lotte Strauss, New York.
Patent Ductus Arteriosus with Reversal of Shunt, Samuel O. Sapin, New York.
Ectopia Cardis Reversa: A Very Rare Congenital Anomaly of the Heart, Bruno Z. Kisch, New York.
Present Status of Surgery for Pulmonic Stenosis, Robert P. Glover, Philadelphia.
Surgical Treatment of Coarctation of the Aorta, F. Henry Ellis and Oscar T. Clagett, Rochester, Minn.
Surgical Closure of Interventricular Septal Defect, Earle B. Kay, Cleveland.
Surgery of Interatrial Septal Defect, with Special Reference to the Use of a Mechanical Heart, F. Dewey Dodrill, Detroit.
Management of Interatrial Septal Defect, Joseph Gaglione and Henry A. Zimmerman, Cleveland.
Treatment of Infected Patent Ductus Arteriosus, Arthur S. W. Touroff, New York.

Admission is free for members and fellows of the college and for interns, residents, and medical students; registration for nonmembers, $3.

Military Surgeons Meet in Washington.—The Association of Military Surgeons of the United States will hold its 60th annual meeting at the Statler Hotel, Washington, D. C., Nov. 9-11, under the presidency of Rear Adm. Winchell McK. Craig (MC), U.S.N.R., Rochester, Minn. The following papers will be presented Monday morning in the Presidential Ballroom:

Recent Advances in Military Medicine, Major Gen. George E. Armstrong, Washington, D. C.
Military Medicine of the Future, Rear Adm. H. Lamont Pugh, Washington, D. C.
Military Medicine and the Air Force, Major Gen. Harry G. Armstrong, Washington, D. C.
Military Medicine and the U. S. Public Health Service, Surgeon General Leonard A. Scheele, Washington, D. C.
Current Medical and Hospital Program of the Veterans Administration, Vice Adm. Joel T. Boone, Washington, D. C.

At 12:30 p. m. Col. Nell Wickliffe (WMSC), U. S. Army, chief, Women's Medical Specialists Corps, Department of the Army, will present a paper, "Recent Contributions of Women Medical Specialists to Military Medicine," after which Colonel Jack Buell (MSC), U.S.A.F., special projects officer, Office of the Surgeon General, Department of the Air Force, will describe "Recent Contributions of Medical Service Corps to Military Medicine." A panel meeting will be held in the Federal Room Wednesday, 1:30 p. m., with the following program: (1) "Medical Manpower—Needs and Utilization," Dr. Edward J. McCormick, Toledo, Ohio, A. M. A. President; (2) "Medical Manpower and Utilization—OSD Viewpoint," Dr. Melvin A. Casberg, Washington, D. C., assistant to the Secretary of Defense (health and medical); and (3) "Federal Health Personnel—Needs and Utilization," Brig. Gen. Howard A. Rusk (MC), U.S.A.F., New York, chairman, Health Resources Advisory Committee. Panel discussants include Drs. Morris Fishbein, and Paul R. Hawley, Chicago, Herbert Ramsey, Washington, D. C., Chester S. Keefer, Boston, Walter B. Martin, Norfolk, Va., A. M. A. President-Elect, and Major Gen. Howard McC. Snyder (MC), U. S. Army, Washington, D. C., physician to the president.

Occupational Therapists Meet in Houston.—The American Occupational Therapy Association will hold its annual convention at the Shamrock Hotel, Houston, Texas, Nov. 13-20. A preconference institute on research in occupational therapy will be given Monday, 9 a. m. Dr. Ben L. Boynton, Houston, Texas, will serve as moderator for a panel on evaluation of suggested research topics. Dr. Stanley W. Olson, dean, Baylor University College of Medicine, Houston, will give the address of welcome during the general program Tuesday afternoon, which has as its subject, "Refining Our Resources." Dr. Boynton's speech on Wednesday morning will be followed by "Present Treatment in Tuberculosis" by Dr. William S. Schwartz, Oteen, N. C. Lt. Col. Charles D. Shields, chief, physical medicine service, Brooke Army Hospital, Fort Sam Houston, San Antonio, Texas, will be moderator for the Wednesday afternoon session when current trends in the treatment of burns will be discussed by a representative of the surgical research unit of the hospital. Thursday morning Dr. Eugene C. McDanald, Galveston, Texas, will have as his subject, "Group Work Practices—Their Application in O. T." Moderator for the Thursday afternoon session will be Dr. Oscar O. Selke Jr., Houston, Texas. Dr. William S. Fields, Houston, Texas, will present "Practical Considerations in the Treatment of Epilepsy," and Dr. Margaret Watkins, Dallas, Texas, will speak on trends in the treatment of the cerebral palsied. Dr. Warren T. Brown, Houston, Texas, will act as moderator for the closing program Friday, 9 a. m. to 12 noon, at which "Problems and Functions of a Respiratory Center" will be presented by Dr. William A. Spencer (and staff), Houston, Texas.

Public Health Association Meeting in New York.—The American Public Health Association and 40 related groups will meet in New York Nov. 9-13. The majority of the sessions will be held in the Statler Hotel and the New Yorker. The registration fee is $4. A panel on world health and the American people is scheduled for the opening day, when a report on the state of the world's health will be given by World Health Organization representatives at a luncheon. The first general session will convene at the Hotel Statler, Wednesday, 8:30 p. m. Addresses of welcome will be given by Drs. John F. Mahoney, New York, and Herman E. Hilleboe, Albany, commissioner of health of New York City and New York State, respectively. Greetings from Scotland will be offered by Sir Andrew Davidson. Dr. Wilton L. Halverson, San Francisco, will deliver the presidential address. The second general session, which will be held Thursday, 3 p. m., will have as speaker Dr. T. Duckett Jones, New York, whose topic will be "Research in the Service of Health." Monday, 9:30 a. m., Dr. Arthur M. Sutherland, New York, will discuss "Psychological Impact of Cancer and Cancer Surgery," and Dr. Walter E. Batchelder, Providence, R. I., will present "Current Emphasis in the Cancer Control Program of the American College of Surgeons" for the Public Health Cancer Association. The Conference of Professors of Preventive Medicine will have a luncheon and afternoon session Monday in the Panel Room, New Yorker Hotel. Dr. R. Percy Vivian, Montreal, Canada, will speak on advances in the teaching of preventive medicine (intramural) and Dr. Henry J. Bakst, Boston, will present extramural advances. Dr. John P. Hubbard, Philadelphia, will give "Highlights of the World Conference on Medical Education: Section on Preventive and Social Medicine." Tuesday morning speakers before the industrial hygiene section will include Drs. Joseph E. Martin Jr., Elkins, W. Va., Herbert K. Abrams, Berkeley, Calif., and Irving R. Tabershaw, Forest Hill, N. Y. "Training Physicians for School Health Service" will be considered by Drs. Robert W. Culbert Jr. and Harold Jacobziner, New York, and Philip Ollstein, Brooklyn, for the school health section at the Statler Hotel. Tuesday afternoon the epidemiology section will hear Dr. James K. Shafer, Washington, D. C., outline "Ten Years of Progress in the Treatment of Syphilis," and Drs. Theodore Rosenthal and Abraham Oppenheim, New York, discuss "Epidemiology of Cancer." Friday morning Dr. George G. Reader, New York, will talk on organization and development of a comprehensive care program before the medical care section, and Dr. George A. Silver, New York, will give "The Family Health Maintenance Demonstration." Among the participants in the second special session, which will close the meetings Friday, 2:30 p. m., in the ballroom of the Statler with a panel entitled "Public Health—Product of Community Action," will be Drs. Reginald M. Atwater, New York, moderator, Harold M. Erickson, Portland, Ore., John D. Porterfield, Columbus, Ohio, and George Rosen and Samuel M. Wishik, New York.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 5-10. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland 1, Secretary.

American Academy of Obstetrics and Gynecology, Netherland Plaza Hotel, Cincinnati, Dec. 14-16. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago 3, Secretary.

American Academy of Tropical Medicine, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. E. Harold Hinman, University of Puerto Rico, School of Medicine, San Juan 22, P. R., Secretary.

American Public Health Association, Hotel New Yorker and Hotel Statler, New York, Nov. 9-13. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American School Health Association, Hotel New Yorker, New York, Nov. 9-13. Dr. A. O. DeWeese, 515 East Main St., Kent, Ohio, Secretary.

American Society of Tropical Medicine and Hygiene, Brown Hotel, Louisville, Ky., Nov. 12-14. Dr. John E. Larsh Jr., University of North Carolina, School of Public Health, Chapel Hill, N. C., Secretary.

Association of Military Surgeons of the United States, Hotel Statler, Washington, D. C., Nov. 8-11. Dr. R. R. Sayers, Armed Forces Institute of Pathology, Washington 25, D. C., Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 11-12. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Conference of Public Health Veterinarians, Hotel New Yorker, New York, Nov. 9. Dr. James Lieberman, U. S. Public Health Service, Washington 25, D. C., Secretary.

Congress of Neurological Surgeons, Roosevelt Hotel, New Orleans, Nov. 12-14. Dr. B. W. Cannon, 1092 Madison Ave., Memphis, Tenn., Secretary.

Inter-Society Cytology Council, Philadelphia, Nov. 19-20. Dr. Paul F. Fletcher, 634 North Grand Blvd., St. Louis 3, Secretary.

National Society for Crippled Children and Adults, Palmer House, Chicago, Nov 12-14. Mr. Lawrence J. Linck, 11 South LaSalle St., Chicago 3, Secretary.

National Society for the Prevention of Blindness, New York, Dec. 18. Dr. Franklin M. Foote, 1790 Broadway, New York 19, Executive Director.

North Pacific Surgical Association, Victoria, B. C., Nov. 20-21. Dr. John A. Duncan, 509 Olive Way, Seattle, Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 13-18. Dr. Donald S. Childs, 713 East Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

- Michigan, H. H. Rackham Auditorium, Ann Arbor, Dec. 5. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Governor.
- Midwest—Ill., Ind., Iowa, Minn., Wis.—Hotel Schroeder, Milwaukee, Nov. 21. Dr Francis D. Murphy, 536 West Wisconsin Ave., Milwaukee 3, Chairman.
- North Carolina, Chapel Hill, Dec. 3. Dr. Elbert L. Persons, Duke Hospital, Durham, Governor.

Regional Meetings, American Rheumatism Association:

- Ohio and Western Pennsylvania, Mayflower Hotel, Akron, Ohio, Nov. 11. Dr. Roger Q. Davis, 1405 Goodyear Blvd., Akron 5, Ohio, Chairman.

Southern California Psychiatric Society, Hotel Statler, Los Angeles, Nov. 14. Dr. Jerome M. Kummer, P. O. Box 305, Santa Monica, Secretary.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 8-10. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

Western Surgical Association, The Drake, Chicago, Dec. 3-5. Dr. Michael Mason, 154 East Erie St., Chicago 11, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

British Medical Association, Glasgow, Scotland, July 1-9, 1954. Dr. A. MacRae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Conference of International Union Against Tuberculosis, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

Congress of International Association for the Prevention of Blindness, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

Congress of International Society of Surgery, Paris, France, May 21-22, 1954. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress of Clinical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A. Moore, Washington University School of Medicine, St. Louis 10, Missouri, U. S. A., Chairman, Committee on Arrangements.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hematology, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6ᵉ, France, Secretary.

International Congress of the History of Medicine, Rome and Salerno, Italy, Sept. 13-20, 1954. For information write: Segreteria XIV Congresso Internazionale di Storia della Medicina, Instituto di Storia della Medicine, Citta Universitaria, Rome, Italy.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni Venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of Industrial Medicine, Naples, Italy, Sept. 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Policlinico, Naples, Italy, Chairman, Organizing Committee.

International Congress of Internal Medicine, Stockholm, Sweden, Sept. 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, Sweden, Secretary-General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois, U. S. A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

International Congress of Nutrition, Amsterdam, Netherlands, Sept. 14-18, 1954. For information write: Dr. M. van Eekelen, Centraal Instituut voor Voedingsonderzoek T.N.O., 61 Catharynesingel, Utrecht, Netherlands.

International Congress on Obstetrics and Gynecology, Geneva, Switzerland, July 26-31, 1954. Dr. H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

International Congress of Ophthalmology, University of Montreal and McGill University, Montreal, Canada, Sept. 10-11, 1954, and Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 12-17, 1954. Dr. William L. Benedict, 100 First Avenue Building, Rochester, Minnesota, U. S. A., Secretary-General.

International Congress of Orthopedic Surgery and Traumatology, Berne, Switzerland, Aug. 30-Sept. 3, 1954. For information write: Professor M. Dubois, Isle-Hospital, Berne, Switzerland.

International Congress of Psychology, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N. J., U. S. A.

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Poliomyelitis Congress, Rome, Italy, Sept. 6-10, 1954. Mr. Stanley E. Henwood, 120 Broadway, New York 5, N. Y., U. S. A., Executive Secretary.

International Society of Blood Transfusion, Paris, France, Sept. 12-19, 1954. For information write: Colonel Julliard, Societe Internationale de Transfusion Sanguine, 53 Boulevard Diderot, Paris 12ᵉ, France.

International Society for Cell Biology, Leiden, Netherlands, Sept. 2-9, 1954. Professor Peter J. Gaillard, University of Leiden, Leiden, Netherlands, Secretary.

International Society of Geographical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Professor Fred C. Roulet, Hebelstrasse 24, Basle, Switzerland, Secretary-General.

World Medical Association, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, July 16, 1954. Sec., Dr. Curtiss B. Hickox, 80 Seymour St., Hartford 15.

American Board of Internal Medicine: *Oral.* Chicago, Nov. 30-Dec. 2. The closing date for acceptance of applications was April 1. *Written.* October 19. The closing date for acceptance of applications was May 1. Exec Sec.-Treas, Dr. William A. Werrell, 1 West Main St., Madison 3.

American Board of Neurology and Psychiatry: *Psychiatry and Neurology.* Dec. 14-15. Applications no longer being accepted. Chicago, April 29-30. Final date for filing application is Feb. 1. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Obstetrics and Gynecology: Written examination and review of case histories for all candidates will be held in various cities of the United States, Canada, and military centers outside the continental United States on Feb. 5. Case abstracts are to be sent by the candidate to the Secretary as soon as possible after receiving notification of eligibility to the Part I written examination. Application for reexamination in Part II must be made prior to Feb. 1 of any year. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Various Centers, January 25-26, 1954. Final date for filing applications was July 1. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 20-22. Final date for filing application was August 15. Final date for filing application for Part I is Nov. 30. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Pediatrics: *Oral.* Indianapolis, Dec. 4-6. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Radiology: *Oral. Radiology, Roentgenology, Diagnostic Roentgenology and Therapeutic Radiology.* Chicago, Dec. 6-11. Final date for filing application was July 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

DEATHS

Swift, Homer Fordyce ⊕ New York City; born in Paines Hollow, N. Y., May 5, 1881; University and Bellevue Hospital Medical College, New York, 1906; formerly assistant in pathology and instructor in dermatology at his alma mater; associate professor of medicine at Columbia University College of Physicians and Surgeons, 1914-1917, and Cornell University Medical College, 1917-1919 (on leave); joined the Rockefeller Institute in 1919 as an associate member, was made a member in 1922 and served in this capacity until 1946 when he became a member emeritus; served in France during World War I and was a member of the American Red Cross Trench Fever Commission; consultant to the Secretary of War during World War II; chairman of the general advisory committee for the cardiac program of the New York State Department of Health since 1941; chairman of the American Council on Rheumatic Fever, 1945-1946; member of the Association of American Physicians, American Society for Clinical Investigation of which he was president in 1928, New York Academy of Medicine, Society of American Bacteriologists, American Society of Immunology and the Harvey Society, serving as its president in 1925-1926; in May, 1953, the American Rheumatism Association bestowed on him its distinguished service award for research in rheumatic fever; a member of the Alpha Tau Omega, Nu Sigma Nu, Theta Nu Epsilon and Alpha Omega Alpha; fellow of the American Association for the Advancement of Science; assistant resident physician, 1910-1912, resident physician, 1912-1914, and physician to the Hospital of Rockefeller Institute for Medical Research, 1942-1946, when he became an emeritus member; member of the Council of the New York University from 1942 to 1946; member of the board of directors of the Russell Sage Institute of Pathology from 1923 to 1948; Kober lecturer, Georgetown University Medical School, Washington, D. C., in 1949; contributor to "Forchheimer's Therapeusis of Internal Diseases," "Musser and Kelly's Practical Treatment," "Nelson's Loose-Leaf Medicine," "Oxford Loose-Leaf Medicine," "Cecil's Text-Book of Medicine," and "Mycotic Infections of Men" (Dubos); received the honorary doctor of science degree from New York University in 1931; recipient of medallion of meritorious service award given by the Alumni Federation of New York University in 1933; died Sept. 24, aged 72.

Golub, Jacob Joshua ⊕ New York City; born in Russia July 25, 1891; Boston University School of Medicine, 1915; medical director and executive vice-president of the Hospital for Joint Diseases, for 23 years, from 1929 until his retirement in March, 1952; was in the field of hospital administration and hospital planning for 36 years; physician in the U. S. Public Health Service from 1918 to 1920; medical and health commissioner for Volhynia, Ukraine, of the American Joint Distribution Committee from 1921 to 1923 when he went to Poland in a similar capacity; served on other overseas missions for the committee, and at the time of his death was chairman of its health committee for war stricken areas; in 1924-1925 and again in 1928-1929 medical director of the Beth Moses Hospital in Brooklyn; assistant director of the Mount Sinai Hospital, 1926-1927; consultant in planning of the Rothschild-Hadassah Hospital and Hebrew University Medical School in Jerusalem, Palestine; since 1939 a member of the New York Saratoga Springs Authority and Commission; vice-president of the Hospital Council of Greater New York and for several years was the chairman of the master plan committee; member of the council on hospital planning of the American Hospital Association; member of the New York State Committee of the National Association for Practical Nurse Education, New York Academy of Medicine, American Public Health Association and the New York Hospital Association; charter member of the American Association for Hospital Consultants; died in Mount Sinai Hospital Sept. 23, aged 62.

Andronis, Nicholas, Galveston, Texas; University of Texas School of Medicine, Galveston, 1918; formerly on the faculty of his alma mater; served as secretary of the Galveston County Medical Society; for many years associated with the U. S. Public Health Service; died in Houston May 19, aged 62, of cancer of larynx with metastasis to regional lymph nodes and liver.

Bean, John Lacy, Vinita, Okla.; St. Louis College of Physicians and Surgeons, 1899; died Sept. 5, aged 78, of cerebral thrombosis and fracture of hip.

Black, Allan Brown, Paulsboro, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1896; died Aug. 26, aged 78, following an operation for adenocarcinoma of the stomach.

Bobo, Arlington Henry ⊕ Covin, Ala.; University of Alabama School of Medicine, Mobile, 1911; formerly practiced in Demopolis, where he was director of the Commercial National Bank; died in McNease and Robertson Hospital in Fayette, Sept. 1, aged 67.

Brown, Homer Scott ⊕ Sutton, W. Va.; College of Physicians and Surgeons, Baltimore, 1908; died Sept. 24, aged 72, of a heart attack.

Brummette, James Sutton ⊕ Lieut. Col., U. S. Army, retired, Orlando, Fla.; University of Louisville (Ky.) Medical Department, 1909; served during World Wars I and II; retired March 31, 1942; died in the Walter Reed Army Hospital, Washington, D. C., May 20, aged 70, of carcinoma of the bladder.

Clymer, George, Longmeadow, Mass.; Harvard Medical School, Boston, 1911; member of the New England Society of Psychiatry; served on the staff of the Massachusetts General Hospital in Boston; died Aug. 4, aged 70, of cancer of the liver.

Cook, Frances Helen ⊕ Chicago; Bennett Medical College, Chicago, 1911; died in Women and Children's Hospital Sept. 29, aged 80, of carcinoma of the breast.

Curtis, Alfred Lee, Atlanta, Ga.; Atlanta Medical College, 1891; also a druggist; died Aug. 28, aged 83, of uremia.

Dayton, George Farbridge ⊕ New York City; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Germany, 1909; served on the staffs of the Mount Sinai and Lincoln hospitals; died Sept. 21, aged 65, of embolism.

Dewey, Leonard Adolph ⊕ Seattle; University of Nebraska College of Medicine, Omaha, 1928; specialist certified by the American Board of Preventive Medicine and Public Health; served during World War II; chief of the division of epidemiology and venereal disease control, Washington State Department of Health; formerly epidemiologist for the New Mexico Board of Health; died in Swedish Hospital Sept. 8, aged 50, of amyotrophic lateral sclerosis.

Steele, Edson Hun ⊕ Los Angeles; Albany (N.Y.) Medical College, 1919; associate clinical professor of psychiatry at College of Medical Evangelists; specialist certified by the American Board of Psychiatry and Neurology; fellow of the American College of Physicians; member of the American Psychiatric Association; served during World War II; affiliated with Los Angeles County Psychopathic Hospital; died June 23, aged 58, of subarachnoid hemorrhage.

Stewart, John Noel ⊕ Santa Maria, Calif.; University of Nebraska College of Medicine, Omaha, 1932; died July 18, aged 44, of carcinoma of the pancreas.

Worley, John R. ⊕ Dallas, Texas; University Medical College of Kansas City, Mo., 1909; died June 26, aged 74, of cerebral thrombosis.

⊕ Indicates Member of the American Medical Association.

GOVERNMENT SERVICES

ARMY

Colonel Ash Receives Award.—At the annual meeting of the American Society of Clinical Pathologists in Chicago, Oct. 12-16, Col. James E. Ash (MC) retired, Washington, D. C., received the Ward Burdick award, a gold medal in memory of Dr. Ward Burdick, first secretary of the society, who died in office in 1928. This award is bestowed on the person judged to have made outstanding contributions to clinical pathology, and it was presented to Dr. Ash for his work in establishing an educational program for tumor and tissue diagnosis, which has been of great aid to clinical pathologists. After a meeting with Dr. Frederick Lamb of Davenport, Iowa, Dr. Ash, then curator of the Army Medical Museum, gave consideration to the problems that Dr. Lamb outlined and suggested that the museum might be used for preparation of material to be sent to pathologists. Dr. Ash was instrumental in building up the annual slide seminars now conducted in each state, which are credited with improving the diagnostic ability of pathologists. Since the institution of this educational program, membership in the society has grown from 15 to 900 members in 20 years.

Staff Program at Medical Center in Texas.—Dr. James G. Golseth, associate professor of physical medicine, University of Southern California, Los Angeles, and a specialist in electronics as applied to that field, was the principal speaker before the staff at the Brooke Army Medical Center, Fort Sam Houston, Texas, on Oct. 15. His subject was the problem of peripheral nerve and anterior horn cell lesions in military medicine. Dr. Golseth discussed the use of electromyography in military medicine with special application to peripheral nerve lesions. Lieut. Col. John H. Kuitert, chief of the physical medicine service at Brooke Army Medical Center, opened the program with statistics and other data establishing the problem. Lieut. Col. George J. Hayes, chief of the hospital's neurosurgery section, discussed the emergency management of injuries of the extremities with peripheral nerve involvement.

Personal.—Col. Ernest A. Brav of Philadelphia was recently named chief of the Walter Reed Army Hospital orthopedic service in Washington, D. C. For the past three years, he served in the same position at Letterman Army Hospital, San Francisco, and during that time, he also was an assistant professor of orthopedic surgery at Stanford University.——Col. Edwin S. Wallace (MC), has been named executive officer at Brooke Army Medical Center, Fort Sam Houston, Texas.

NAVY

Surgeon General's Symposium.—The Surgeon General's Symposium for senior officers of the medical department will be held at the National Naval Medical Center, Bethesda, Md., Nov. 5-7. The symposium affords an opportunity for officers commanding the Naval medical department facilities throughout the world to meet and discuss problems associated with the efficient operation of the Navy medical department. Personnel procurement, finance, hospital administration, planning and logistics, the problems of a current and recurrent nature associated with the operation of a military medical department, and the latest developments in military medicine will be presented. The Assistant Secretary of Defense for Health and Welfare, Dr. Melvin A. Casberg, the Surgeon General, Rear Adm. Lamont Pugh, the Commanding Officer, National Naval Medical Center, Rear Adm. Leslie O. Stone, the assistant chief, Bureau of Medicine and Surgery, Rear Adm. Clarence J. Brown, and Rear Adm. Daniel W. Ryan, Dental Corps, chief of the dental division, among others, will participate. Panel discussions of the three day symposium will be held during the afternoon sessions.

PUBLIC HEALTH SERVICE

Personal.—Dr. Howard A. Rusk, chairman, Department of Rehabilitation and Physical Medicine, New York University College of Medicine, has been appointed to serve on the National Advisory Arthritis and Metabolic Diseases Council, Surgeon General Scheele announced Oct. 16.

VETERANS ADMINISTRATION

Grants for Wheelchair Homes for Veterans.—Federal grants for wheelchair homes totaling more than 29 million dollars have been made to 3,123 seriously disabled veterans, including those of the Korean conflict, the Veterans Administration announces. Another 1,735 veterans have received preliminary approval for such grants. All veterans of war or peacetime service since 1898 who cannot get about without the aid of such devices as wheelchairs, braces, crutches, and canes, may be entitled to these special grants. These veterans must be entitled to compensation for permanent and total service-connected disability for the loss, or loss of use, of both legs due to certain specified conditions. The VA defrays 50% of the cost of wheelchair homes for eligible veterans up to a maximum of $10,000 under grants first authorized by Congress in 1948. Such special features as ramps, doorways that will accommodate a wheelchair, special bathroom fixtures, and exercise rooms equipped to meet the needs of the individuals are incorporated into these homes. The grants may be used in several ways. The veteran may buy a lot and build on it, remodel his present home to suit his needs, or apply the grant against his mortgage if he already has a suitable home. As of Aug. 31, a total of 6,167 veterans had made applications for the grant. The VA gave preliminary approval to 4,858.

Residencies Available.—Vacancies are available for residents in head and neck surgery and otolaryngology at the Veterans Administration Hospital, 130 West Kingsbridge Road, Bronx 68, New York. The residency is approved for three years and is supervised by consultants from affiliated medical schools. A basic science course is included in this program. Instruction during the three years also includes endoscopy, allergy and plastic surgery of the nose. Salaries range from $2,640 to $3,300 per annum. Veterans receive preference, but applicants need not be veterans. For information write to Liaison Officer, Deans Committee, Veterans Administration Hospital, 130 West Kingsbridge Road, Bronx 68, N. Y.

Geriatrics Symposium.—A two day geriatrics symposium sponsored by the Veterans Administration and the Peninsula Academy of Medicine was held at Chamberlin Hotel, Old Point Comfort, Virginia, Sept. 24-25. Among those on the program were Drs. Edward J. Stieglitz, Washington, D. C.; Lloyd Thompson, Winston-Salem, N. C.; George M. Piersol, Philadelphia; Walter O. Klingman, Charlottesville, Va.; Reno R. Porter, Richmond, Va.; and I. Jay Brightman, Albany, N. Y. The program on Sept. 25 was comprised of contributions of physical medicine and vocational rehabilitation, cardiovascular conditions in the aged, and certain surgical aspects, including management of amputees.

Personal.—Dr. Claud E. Carter has been appointed manager of the Veterans Administration Hospital at Fort Bayard, N. Mex. Dr. Carter was formerly chief of professional services at the 222-bed tuberculosis hospital at Fort Bayard.

FOREIGN LETTERS

BRAZIL

Surgery of Duodenal Ulcers of the Posterior Wall.—There are still several problems related to the surgical treatment of the duodenal ulcers penetrating into the capsule or even the parenchyma of the pancreas. In order to contribute to a better understanding of these problems, Dr. Piragibe Nogueira and Dr. Luis Barker, assistant professors of clinical surgery at the São Paulo State University, dissected 17 of 22 specimens sent to them by the department of pathology and reported their findings in *Revista Brasileira de Medicina* (42:405, 1953). They pointed out that the dissection of the posterior wall of the duodenum below the ulcer's crater should be limited to 1 cm. or a little more. This is because the nutrition of the duodenum, from the aboral half of its first portion, depends exclusively on vessels, well separated and not forming an anastomotic net, that originate at the duodenopancreatic arcades and penetrate into the duodenum. The dissection should be made between the submucous and muscular layers, because by this means it is performed in the thickness of the posterior duodenal wall. This dissection is easily performed, avoids trauma of the pancreas, and keeps far from the common duct and the accessory pancreatic duct. Besides, it has the great advantage of avoiding the ligature of any of the two arteries of the upper pedicle (branches of the gastroduodenal artery). This opinion is based on their finding, in the 17 dissections they have performed, that frequently there is a marked predominance of the arteries of the upper pedicle in the arterial nutrition of the duodenum. The predominance was of such a degree that in 4 out of 17 cases the ligature of the anterior artery of the upper pedicle would cause circulatory deficiency in the first and second portions and even in a part of the, third portion, reducing blood supply.

The authors believe that many patients reported as having had acute pancreatitis who died in the immediate postoperative period of extensive and deep penetrating duodenal ulcers had necrosis caused by the ligature of one or both arteries of the upper pedicle in the presence of a limited blood supply to the lower pedicle. During their study they found out that necrosis may be caused either by the small diameter of the arteries of the lower pedicle or by the absence of arcades and sufficient anastomoses between the two pedicles. This fact is in favor of the submucous dissection procedure, which protects the branches of the gastroduodenal artery.

Improvements in Indications for Pneumonolysis.—Drs. Octavio Nebias, E. J. Zerbini, and B. Fleury de Oliveira reported to the Associação Paulista de Medicina on improvements in the indications for pneumonolysis (Jacobeus' operation). In their practice at the São Luis Gonzaga Hospital of Jaçanã, São Paulo, they used the operation from 1936 to 1951 in a total of 1,882 cases. Until 1941, every pleural adhesion was considered an indication for cautery regardless of the kind of lung collapse and the evolution of the tuberculous lesion. The operation would be performed as soon as possible and the number, breadth, and shape of the adhesions were never contraindications for their section. Under these conditions, 664 operations were performed, with 64.8% good results and 35.2% fair or bad results. The following complications were observed: pleural effusion, 28%; pleural symphysis, 13.3%; empyema, 7.5%; and bleeding, 5.7%. To improve these results, some modifications were introduced in the indications for pneumothorax and cautery pneumonolysis. The cortical and insufflated cavities as well as the strong and large pleural adhesions were not considered indications for pneumonolysis and the operation was not performed unless the evolution of the pulmonary lesion could be evaluated. In 200 consecutive cases of this second group, 73.5% obtained good results and 26.5% fair and bad results, with the following complications: pleural effusion 16%, pleural symphysis 2.5%, and hemorrhage, 3%.

Pathogenesis of Inguinal Hernia.—Several papers in the medical literature on the cause of inguinal hernia have suggested a definite relationship between this condition and some modification of the pelvic shape. Drs. Fabio S. Goffi, Guilherme M. Leite, and P. Lacerda Pinto, of the department of experimental surgery, São Paulo State University, published in *Revista Paulista de Medicina* (43:1, 1953) a study on 76 men in whom measurements of the pelvic diameters were made. These men were (1) patients with indirect inguinal hernia (34); (2) patients with direct inguinal hernia (21); and (3) patients without inguinal hernia (23). The results were studied statistically by means of the *t* Student's test, no significant difference having been found between the length of each diameter in those three groups. Measurements of the level of insertion of the lower fibers of the obliquus internus muscle were taken on patients with inguinal hernia who were operated on. There was no significant difference in the level of origin of the lowest fibers from the inguinal ligament in the two groups with direct or indirect hernia. However, there was a significant difference in the levels of the medial insertion of the lowermost fibers of the obliquus internus muscle. In the patients with direct hernia, that level was higher than in patients with external oblique hernia.

Eosinophilic Granuloma of the Skin.—Dr. Jorge Lobo, of the University of Recife, Pernambuco, described a case of eosinophilic granuloma of the skin that he believes is the first of its kind to be reported in South America. A 47-year-old woman had a generalized malignant tumor and died 10 months after the onset. The disease as described showed a marked similarity with the condition described by Wiedman in 1947, and did not follow the perioral pattern presented by Nanta, Pautrier, and Labourgade. The most important histological feature of the case was a polymorphous granulomatous state with numerous eosinophils with phagocytosis of hemosiderin, and a marked perivascular infiltration and thickening of the intima of the blood vessels. In addition epithelioid cells and gigantocytes were observed. Foamy cells were not observed. The author considered his case to be closely related to the reticuloses. The differential diagnosis should be made from erythema elevatum diutinum, from which the condition described by Dr. Lobo differs in the predominance of eosinophils over neutrophils.

CHILE

Pressure Reactions to Effort and to Cold.—In *Revista Medica de Chile* for April, 1953, Prof. L. Herve and Dr. G. Kunstmann report a study of 138 persons with normal cardiovascular systems. Persons over 60 and under 16 years of age were eliminated. The average age was 32.4 years. There were 91 men and 47 women. In all persons, a strict check-up was made to eliminate those with possible cardiovascular lesions. This check-up included personal and family history, physical examination, radiologic tests, and neurological, electrocardiographic, and eye fundi examination. No blood pressure reading was performed until at least 2½ hours after the person had eaten and 1 hour after he had smoked a cigarette. Readings were performed at various intervals to eliminate psychic reactions. Hines classic cold pressure test was performed. Pressures were read every minute during the first five minutes and every five minutes during the next 15 minutes. A standard effort test was made. The frequency of the readings was similar to that in the former method.

The results of the measure of blood pressure in the superior and inferior extremities were similar to those obtained by other authors. The systolic pressure was generally 10 mm.

The items in these letters are contributed by regular correspondents in the various foreign countries.

higher in the tibial than in the humeral artery. It has a tendency to increase with age, but this increase is greater in the inferior extremities. The diastolic pressure (oscilometric method) is slightly lower in the inferior than in the superior limbs. The median blood pressure was practically the same in the humeral and in the tibial arteries. Postural changes produce great tensional variations. The change from the dorsal decubitus to the vertical position produces an increase in the systolic pressure, in the tibial region, of 88 mm. and in the diastolic reading of 67 mm. This increase is greater in tall persons. Systolic pressure in the arm did not show important variations with the change of posture, whereas the diastolic pressure showed an 8 mm. increase. The results obtained with the pressure tests can be summarized in the following manner:

Effort Test.—The effort test was performed in 54 normal subjects. The analysis of the data reveals certain differences in the tensional reactions of the superior and inferior extremities. In the arm, there is always a hypertensor reaction of the systolic reading, whereas, in the lower limb, there is an absence of systolic hypertension in some cases (7.4%) and even a decrease of the reading in certain other cases (5.5%). The diastolic readings were subject to even greater variations than the systolic. In the lower limb, increase was present in 27.7% of the cases, no change was registered in 33.3%, and a decrease was present in 38.8%. The humeral readings showed an increase of 50%; 18.5% of the persons tested showed no change and 31% had a lowering of the diastolic pressure.

Cold Pressure Test.—This test was performed in 53 persons. The changes in the maximum pressure are, in general, greater in the inferior extremities than in the superior. The variations of the diastolic readings, however, are rare and very similar in the superior and inferior limbs. In 55% of the subjects, there was a normal reaction in both the superior and inferior extremities. Hyperreaction of both the superior and inferior limbs was present in 26.4%; hyperreaction of the arms and normoreactions of the feet was present in 5.6%. Hyperreactions of the inferior extremities and normal readings of the humerals were present in 13.2%.

After trying to establish some relationship between the effort and cold tests, the authors conclude that the reactions to effort are different from those to cold inasmuch as their intensity and their duration are greater and longer. These tensional variations are not, however, statistically significant.

Chronic Nonspecific Ulcerative Colitis.—After analyzing the symptomatology of this clinical entity, Dr. H. Orrego and associates go on to study its pathological anatomy and radiologic and rectosigmoidoscopic features. In the group studied, the ages varied between 28 and 59 years. The duration of symptoms prior to consultation was from 10 years, the longest, and 10 days, the shortest. Endamoeba histolytica was present in 50% of the cases, and treatment of the amebiasis did not influence the evolution of the disease. The authors agree with Bokus that E. histolytica can produce a crisis in ulcerative colitis. In conclusion, the authors point out that rectosigmoidoscopy is the most valuable method of diagnosis. The personality of the patient with ulcerative colitis was studied by Dr. C. Nunez and co-workers of the psychiatric department of the Catholic University. They conclude that ulcerative colitis is the consequence of prolonged and intense emotional tension. Patients are prone to cyclic depressions that are produced by problems that are apparently very unimportant but that have deep psychological meaning. The psychosomatic approach to this disease is the only valid one.

Radiologic Study of Terminal Ileum in Typhoid.—After describing the technique used, Dr. J. M. Balmaceda and associates present the results obtained in 40 cases studied. Thickening and irregularity of the mucosa was present in 11 patients. Flocculation of barium was observed in 12, atonicity and dilatation of the terminal intestine in 12, and a nodular shadow that might be of lymphatic origin in 3. Two patients did not show any radiologic manifestations. In many of the patients, regression of the radiologic manifestations was observed during the evolution of the disease; in others there was no variation at the time of discharge. Radiologic signs similar to those observed in patients with typhoid were found by the authors in patients with amebiasis or coccidiosis. For these reasons, the authors do not believe that the radiologic manifestations found in patients with typhoid have any practical application.

Postgraduate Courses.—The postgraduate course in internal medicine began on July 1 and lasted until July 31. The lectures on theory were held in the Salvador Hospital, with the exception that those on infectious disease were held in the infectious ward of the Barros Luco Hospital. Practical courses were held in the Salvador Hospital in the section of internal medicine headed by Prof. H. Alessandri; those on infectious disease were held at the Barros Luco Hospital under the guidance of Drs. Horwitz and Kraljevic; and the discussion of physiopathology was conducted by Professor Egana. Among the subjects that were discussed were physiopathology, diagnosis and treatment of shock and of coronary insufficiency, diagnosis and treatment of the most frequent arrhythmias, heart failure, hemodynamics of congenital and acquired heart lesions, interpretation of hematologic examinations, diagnosis of acute nontubercular neumopathies, physiopathology of edema, diagnosis and treatment of chronic diarrhea, physiopathology, diagnosis, and treatment of diabetes, typhoid and paratyphoid, acute meningitis, and lumbago.

The postgraduate course in surgery began on Aug. 3 and continued until Sept. 3. Lectures on theory were held in the Salvador Hospital, and the practical demonstrations were given at the Salvador Hospital by Prof. F. deAmesti and Prof. M. Martínez and at the San Borja Hospital by Prof. A. Constant. Among the subjects presented, gallbladder lithiasis and tumors were given great emphasis. Proctology and thoracic surgery were also discussed.

ISRAEL

Medical History of Our Time.—On the occasion of the Seventh International Congress of the History of Science, Dr. J. Seide, medical director of the Hadassah Hospital, Haifa, has written a survey on "Medical History in Our Time," which was published in part in *Acta Medica Orientalia* of July, 1953. In this survey Dr. Seide says that "it is perhaps the tragedy of the medical profession that it must depend on the knowledge or the ignorance of its own time." This explains the coincidence of crises in medicine with revolutionary periods and the recurring wish of medicine to clarify its principles again and again in a changing world.

The present generation is privileged to witness an unprecedented growth of human knowledge. The advances in medicine are a direct result of application of the experimental method and the discoveries of science to its own needs, yet, as every member of the profession believes, medicine is essentially an art and has never been followed wholly in the scientific spirit.

It is perhaps an unavoidable but nevertheless unfortunate result of modern development that science, although increasing enormously the sum of our knowledge, has brought about also some separation of the different parts of it and consequently also a certain loss of contact between research and practical medicine. At the same time the mass of accumulated detail has grown beyond the power of the individual physician to assimilate. The progressing tendency toward specialization is the necessary result of this development, and there is no reason to expect that this process will be arrested in the future.

True, of some aspects of medicine physicians today know as much or as little as the contemporaries of Hippocrates. Science has, after all, its limitations, especially when concerned with living beings. Ancient knowledge, as far as it is concerned with facts, is seldom of any use, for in medicine there is no return to old methods and prescriptions. "The history of medicine is essentially a history of ideas" (Singer) and as such its value lies in making known some fundamental truths. It teaches first of all modesty, in demonstrating with overwhelming clearness that in science the truth of today is the error of tomorrow. Thus it promotes caution in acceptance of statements without factual evidence; it affords a corrective for the inborn tendency to form hasty and superficial judgments. A historically trained mind is not easily deceived if confronted with ideas that appear new in clever disguise but are really ancient and obsolete. It takes nothing for granted and is critical toward authority, however sacred. Without inductive reasoning, science and medicine would remain sterile no matter how rich in newly discovered details. It is, therefore, to be deplored that the medical student of this day is so deeply immersed in learning facts that he has little time for quiet reasoning. A course in medical history would have great advantages for him; it would extend his mental horizon and correct the view from which he is apt to see contemporary achievements. It would tend to lessen his pride and to make him appreciate more fully the work of other men, be they great or small, famous pioneers and innovators or humble practitioners.

The history of medicine is only a part of the history of civilization and as such is closely interwoven with the general development of humanity. Its study tends to bring the student in touch with many sides of human activity: the life and labors of the people, their beliefs and superstitions, and their aspirations and their needs. This would be a great help in clarifying the position of the medical profession in modern society.

The Israelian people have no reason to be ashamed of their scientific or medical traditions. There were periods in history in which the terms "Jew" and "doctor" were almost synonymous. But all this should not make Israelians forget that they are only a small part of a great whole, and that "the history of science is an essential part of the history not of this or that section of mankind, but of the whole of it" (Sarton).

Medical Problems of Immigration.—Dr. T. Berman reviewed in the *Dapim Refuim* (May, 1953) the medical problems of immigration in Israel, especially as far as the Labor Sick Fund is concerned. According to the review, these problems have been influenced by: (1) the tempo and extent of immigration, (2) the composition of the immigrant population according to country of origin and age groups, and (3) transfer of complete communities in certain countries, conducted without any selection and irrespective of age and the health standard of the immigrants. The first registration of the population in Israel in November, 1948, showed 716,000 persons. By Jan. 1, 1952, the number had reached 1,405,000 persons. There were times when more than 1,000 persons entered the country every day, and it was necessary to separate the healthy from the sick in the reception camps. On April 1, 1951, the percentage of immigrants received from various places were as follows: Europe, 54.7%; Asia, 30.4% (including Turkey, Syria, Iraq, and Yemen); North Africa, 14.3%; and the United States, 0.6%. The age groups of the newcomers differ greatly from those elsewhere, with a greater proportion of the population being under 14 years of age as compared to England and France. On the other hand the number of immigrants in the higher age groups is smaller than elsewhere. The percentage above the age of 60 was 6.8% in Israel, 15.8% in England, and 16.4% in France.

Differences in the countries of origin of the immigrants and age groups affected very much the medical aspects of the immigration. Among European immigrants tuberculosis was particularly prevalent. A total of 325,000 immigrants have been examined by mass radiography by Dr. Lichtenstein. In 1948-1949, when 61% of the immigrants were from Europe, the incidence of active tuberculosis among those examined was 0.8%; in 1950-1951, when the percentage from Europe dropped to 29% of the total, the incidence of tuberculosis decreased to 0.2%. The tuberculous patients among the immigrants have presented the country with the most urgent need of expanding hospitalization. From a total of 590 in 1949 the number of beds by 1951 had increased to 1,645.

The immigrants from Asiatic and North African communities have to a great extent transplanted here the diseases of their countries of origin, such as eye, skin, and children's diseases. The reports of ophthalmologists show that about 20% of all examined were suffering from trachoma, and most of these were children. Among skin diseases particular mention should be made of ringworm, which in many surveys affected 2% of all the examined children. The arrival of whole communities from Asia and North Africa increased infant mortality from 29 per thousand in 1947 to 51 per thousand in 1949. In 1951 this figure dropped to an average of 39 per thousand. There exist, however, notable differences of infant mortality in various types of settlements. The remarkable decrease in mortality of infants in 1951, even in the remote places of the country, shows a significant improvement, but much remains to be done. In spite of unsanitary living conditions, there have been no epidemics, apart from outbreaks of poliomyelitis and diphtheria. The diphtheria rate per 10,000 has been 14 in 1949; 14.7 in 1950, and 19 in 1951. The increase was due to discontinuance of immunization in the presence of an outbreak of poliomyelitis. Since then immunization on a large scale has been accomplished. The outbreak of poliomyelitis started in 1949 among the old, settled population and reached its peak in 1950; there were 14.3 cases per 10,000 persons in 1950 and 6.9 per 10,000 in 1951.

The mortality rate reached 14% of all cases. Comparative notes on morbidity in the old, settled population and the newly established localities have been made out of a population of 80,000 people. These notes should be viewed with reserve because they refer to ambulatory examinations only, but certain facts are too striking to be ignored. The incidence of hypertension in all the national groups compared is almost twice as high among the immigrants of European origin. The same high number of cases of hypertension was found by Dr. Robinson in the displaced-persons camps in Austria. There are great differences in acute intestinal diseases, which are almost three times as prevalent among the immigrants as among the old inhabitants. Children of newcomers show a greater incidence of dystrophy and toxicosis. The ratio between the cases of toxicosis among immigrants and that of old inhabitants is 17 to 1. A problem of particular significance is the undernourishment of many of the children from Asia and North Africa, notably those from Yemen.

LONDON

Magic, Medicine, and Religion.—Writing on the subject of magic, medicine, and religion, Sir Sidney Smith, Regius Professor of Forensic Medicine at the University of Edinburgh (*Brit. M. J.* 2:4815 [April 18] 1953) recalls that disease is as old as life itself and hypothesizes that the primitive medicine man aimed to safeguard life by mysterious rites, herbs, and appeals to a higher power. He then traces these processes from Egypt to Greece and thence to Rome, ending finally with the scientific awakening after the Dark Ages.

Regarding miracles, he points out that much that is commonplace in medicine at present would have previously been regarded as "miraculous." He reminds us that shock treatment of psychiatric diseases is really a "miracle," in that we have no more scientific notion of how the beneficial effects are produced than had the ancients in trephining the skull to exorcise demons.

After consideration of body-mind relationships and psychosomatic medicine, Professor Smith concludes that, notwithstanding modern advances, we are still only at the periphery of knowledge of living processes and that our ignorance of the mind itself is as great as that of the ancients.

Medical Auxiliaries.—An editorial in the *British Medical Journal* (2:1267 [June 6] 1953) deprecates the decision of the Minister of Health not to implement the recommendation of the Cope Committee to set up a system of statutory registration of medical auxiliaries with a central council. Admittedly, there were certain minor disagreements on the part of the almoners, the occupational and speech therapists, and the physiotherapists. The editorial regards as "unfortunate," however, the decision to ignore the weight of opinion. It points out that the public and the medical profession needs a guarantee that medical auxiliaries are properly trained, and that the only way to ensure this is to have a statutory register.

Teamwork in General Practice.—Speaking to the Annual Conference of Local Medical Committees, Mr. McCleod, the Minister of Health, raised enthusiasm by stating that the family doctor must be the leader of the domiciliary health services, able to treat patients in their own homes, away from the unfamiliar grounds of the hospitals. He should also have direct access to x-ray and laboratory facilities. If he does have occasion to refer a patient to hospital for a consultant's opinion, he should receive a prompt notification of the findings.

The *British Medical Journal,* in reporting this, adds that the problems of general practice are not peculiar to this country but are fundamentally identical in all countries with modern medical facilities. The report agrees wholeheartedly that the family doctor should be in the picture as the clinical leader.

After Twenty-Five Years in Medicine.—Writing in the *British Medical Journal* (2:930 [April 25] 1953), Dr. A. Meiklejohn describes an inquiry made by a group of Glasgow University graduates into the fate of nearly 900 fellow students who graduated in the years 1923-1926 and had been in practice for 25 years. The inquiry was by means of a questionnaire, which was answered by 48% of those who received it. Nearly 60% of these were family doctors, while the remainder were equally divided into consultants and those holding full-time appointments. A total of 90% were married, 7% to physicians and 19% to nurses. Nearly one family in two had at least one child entering medicine.

A statistical analysis of the cause of death in the 99 cases (of the total 899) in which it had occurred revealed that there was a significant increase in the number of deaths due to violence and poisoning. The total mortality, however, was less than that of the population of Scotland as a whole.

Asked what were the chief advances in medicine during their careers, the family doctors placed insulin, liver therapy, and diphtheria immunization first. The challenges of our age, they thought, were the care of the aged and chronic sick and the control of tuberculosis.

The Slough Experiment in Industrial Hygiene.—*The Lancet* (1:1241 [June 20] 1953) describes an experiment in industrial hygiene being carried out at Slough. The aim is to promote the health and welfare of workers in local industry.

At the head of the service is Dr. Nash, an American-trained industrial hygienist. He has over 15,000 workers under his care and that of his team, which includes an engineer and a chemist. The whole scheme helps to train students for the Diploma in Public Health of London University.

An important part of the work done deals with industrial hazards, e. g., from fumes or dust, but there is a routine service with a central clinic for industrial casualties that is coordinated with the local hospitals. Ancillary and recuperation services are also provided. It is concluded that there is great need for perhaps a dozen similar units in the United Kingdom.

Mount Everest Climbed.—Using open-circuit oxygen apparatus (reports *The Lancet* 2:1190 [June 13] 1953) Hillary and Tensing conquered Mount Everest on May 29, a few days before the coronation. Previously an attempt with closed-circuit oxygen apparatus had failed. Apparently oxygen supply was the most worrying aspect of the expedition and a tribute is paid to those who planned the oxygen equipment and to the sherpa parties who carried the necessary supplies.

Hallux Valgus.—*The Lancet* (2:000 [June 27] 1953) in an annotation comments that hallux valgus is usually due to badly shaped shoes (although it is seen in persons who do not wear shoes). While there is a tendency towards more sensibly shaped shoes, the shape of shoes is still a long way from the ideal of a straight inner border. The point is made that, although such a shoe may now appear ugly, it is merely a matter of what one is used to; it merely needs a Schiaparelli or Christian Dior to introduce the change overnight.

Psychiatry in General Practice.—In a discussion at the Royal Society of Medicine (April 14) Dr. John Fry gave an account of his experience over a two-year period in a middle-class practice. He found that psychiatric patients comprised 10% of his practice and that this form of illness was the third most prevalent after respiratory and gastrointestinal diseases. Women psychiatric patients outnumbered men by 5:2. About 1% of his practice were incurable neurotics attending time and again, but only a small number of his cases of psychiatric disease were serious enough to refer to hospital.

Dr. Denis Leigh of the Maudsley Hospital thought that the family doctor should diagnose depression earlier than is usually done but that the psychiatrist should be more interested in treatment of cases referred to him and less in simple diagnoses.

TURKEY

Pneumoperitoneum in Pulmonary Tuberculosis.—In the *Turkish Bulletin of Hygiene and Experimental Biology,* vol. 12, no. 3, Prof. Nusret Karasu of Ankara University department of phthisiology and his associate Dr. Ragip Üner have published the summary of their report on pneumoperitoneum therapy in pulmonary tuberculosis presented at the 11th National Medical Congress at Istanbul. Of 136 patients who had pulmonary tuberculosis and who were given pneumoperitoneum in conjunction with antibiotics, very good results were obtained in 51 patients. In 101 patients in whom there were contraindications to pneumothorax and caverns 4 cm. in diameter, the caverns closed and disappeared in 60% within six months after therapy with pneumoperitoneum. In 9% there was no change, and in the other patients the caverns had slightly decreased. Nine patients who did not benefit were given other collapse therapy. Very good results were obtained in 62 patients given pneumoperitoneum before surgical intervention; it arrested the growth of the caverns and prevented diffusion in the surrounding areas. Similar results were obtained in 50% of 47 patients who had caseous forms of tuberculosis in both lobes and a high temperature and who were in serious general condition. Similar results were obtained in 24 patients who had hemoptysis. Two patients with extreme hemoptysis did not benefit from the therapy. Sixty-two patients who had lung infiltrations were given pneumoperitoneum with resultant decrease of lesions and absorption. Forty per cent of the patients who had lobar dorsal tuberculosis, infiltrations, and caverns recovered after pneumoperitoneum therapy. In 19 of 27 patients who had primary tuberculosis, cavities disappeared after pneumoperitoneum was performed as an adjuvant to pneumothorax.

In pregnant women, pneumoperitoneum almost always had a good effect at first, but the effect abated soon after parturition when the diaphragm descended and physiological changes occurred. In order to prevent the diaphragm from descending, 10 patients were given pneumoperitoneum after parturition. Follow-up study revealed that the therapy had a desirable effect in nine patients, but the 10th later died of miliary tuberculosis. In 15 out of 17 patients with miliary tuberculosis, pneumoperitoneum performed during the post-acute stage had a very good effect. Favorable results were also obtained in 12 patients who had empyema. Of 26 children 6 to 12 years old, the majority had serious infiltrations, caseous pneumonia, and primary tuberculosis. Caverns disappeared within six months after pneumoperitoneum, and their general condition improved greatly. These children are now being followed up.

According to other medical publications, complications occur in 8% of the patients. Complications during pneumoperitoneum therapy at the Ankara University clinic were 4%; there were no fatalities. Peritonitis accounted for 1%, ascites 0.1%, hernia 0.1%, hemorrhages in the peritoneum 0.1%, mediastinal emphysema 0.1%, lobal atelectasis 0.2%, subcutaneous emphysema 0.12%, anorexia 3.0%, and loss of weight 0.15%. Air embolus, cardiac insufficiency, appendicitis, cerebral lesions, and torsion of the omentum did not occur.

CORRESPONDENCE

INTERSERVICE UTILIZATION OF EXPERT MILITARY CLINICAL CONSULTANTS

To the Editor:—During the past 18 months, seven Army and Navy medical officers stationed on the island of Puerto Rico have visited Ramey Air Force Hospital in the capacity of clinical consultants. Arrangements were made by the hospital commander in cooperation with the Surgeon, Antilles Command, and the Surgeon, 10th Naval District. Four of these military physicians who have participated on a voluntary basis are still assigned. They are Col. Lowell E. McKelvey (oromaxillofacial), Lieut. Col. Michael J. Hitchko (orthopedic), Lieut. Col. A. J. Bauer (radiology), all of Rodriguez Army Hospital, and Capt. C. K. Youngkin, U. S. N. (dermatology), Surgeon, 10th Naval District.

This small group of military physicians consists of highly qualified specialists, and they have served this Air Force hospital on a voluntary basis. Their value in graduate teaching and in direct care of Air Force personnel stationed here has been great. Although no mention of the fact has been made, it is apparent that the only personal benefit derived from this service is in the exercise of the art of medical consultation for which each has trained himself. In every case, each of these physicians has had almost more than he could adequately cover in his regular assignment. Transportation has been tedious and difficult at times.

In line with the experience gained from this small-scale medical operation, it seems advisable to suggest that each of the three services avail itself of the expert military consultants who are stationed in any area such as the geographical area of the island of Puerto Rico (any area of reasonable transportation radius). Many military physicians of mature age by necessity are losing proficiency in clinical specialty training while in key command and staff assignments. Also, in many Air Force, Army, and Navy headquarters or installations there are specialists who could be made available for utilization at other nearby hospitals on a mutual exchange of expert specialized talent. There should be some administrative machinery set up so that these physicians are utilized more consistently in part-time consultation on a voluntary basis. The first requirement to be met is the creation of incentive followed by some sort of recognition for such voluntary services performed.

It is suggested that an information roster be published for circulation to all command surgeons and hospital commanders throughout the military services, perhaps on a semiannual basis. This roster should include all American board diplomates and, perhaps, all of those now board eligible. Both an alphabetical and a geographical listing would be desirable. Some sort of incentive comparable to that enjoyed by civilian consultants to military hospitals should be devised. The simplest and most effective means would be an official letter or certificate of appointment issued by each surgeon general after a recommendation from a hospital commander has been tendered and approval action taken. Receipt of such an appointment should become an authorized inclusion in efficiency report job descriptions with appropriate narrative comment as to manner of performance (by letter, if necessary). It is believed that extra remuneration is not essential but that standing authority for travel at government expense should be provided explicitly for the purpose of conducting expert medical consultation within specified geographical limitations.

The last and most important essential suggestion for this expert manpower utilization is that of recognition. The military physician who has trained himself, whether privately or at government expense, receives little recognition for his effort except by the awarding of an Air Force specialty classification number that has no meaning outside of a small group of his potential contacts including members of sister services and civilian associates. The issuance of a yearly certificate of appointment and the semiannual publication of an alphabetical and geographical locator roster is in itself a form of recognition. However, all who are appointed will not participate; therefore, those that do should be recognized in some manner. It is suggested that a listing of each active participant be submitted to an appropriate publication, such as Government Services section of The Journal, on a regional or command basis at specified intervals.

Lieut. Col. James H. Hammond, U.S.A.F. (MC)
U.S.A.F. Hospital
Ramey Air Force Base, Puerto Rico

WATERHOUSE-FRIDERICHSEN SYNDROME

To the Editor:—It is reported in an article by Björklund (Fulminant Meningococcus Infection with Purpura: Case With Recovery, *Nord. med.* 49:571 [April 17] 1953; abstracted in *J. A. M. A.* 152:1671 [Aug. 22] 1953) that a 5-year-old girl, moribund for some hours after admission and with shock and postmortem-like lividity, recovered after the use of antibiotics (penicillin and sulfonamides), adrenal cortical extracts, desoxycorticosterone acetate, and vitamins C and K. Pretreatment studies and those carried out during the acute phase of the illness indicated a normal excretion of 17-ketosteroids and 11-oxysteroids. The normal values did not indicate marked, irreversible injury to the adrenal cortex.

Many patients with the Waterhouse-Friderichsen syndrome, however, continue to die in shock, despite the liberal use of antibiotic and chemotherapeutic agents. Treatment of the peripheral vascular collapse during the first 24 to 48 hours remains the major therapeutic problem. Muhl has reported the successful treatment of this phase of the illness with an intravenous infusion of arterenol (Nor-Epinephrine) (Nor-Epinephrine in the Treatment of Acute Meningococcemia with Shock [Waterhouse-Friderichsen Syndrome] and an Evaluation of Adrenocortical Function, *New England J. Med.* 249:229 [Aug. 6] 1953). His patient, with classic Waterhouse-Friderichsen syndrome, recovered. Studies of the adrenocortical function during the acute stage of the illness and after recovery indicated no failure of the adrenal cortex, even in the presence of shock, which responded to arterenol but not to parenteral replacement of adrenocortical substances. Other studies indicate that the Waterhouse-Friderichsen syndrome is not necessarily secondary to acute adrenocortical insufficiency and that the ultimate cause of peripheral vascular collapse is extensive vascular damage with capillary hyaline thrombosis. The use of a continuous infusion of arterenol to maintain a normal blood pressure may be a lifesaving measure.

APPOINTMENTS FOR PHYSICIANS WHO VISIT GREECE

To the Editor:—Before the Public Health Advisory Group of the Foreign Organizations Administration Mission to Greece was terminated last June 30, I had the opportunity of serving as the deputy director; this was a very wide and interesting experience. One of the most pleasant experiences I had involved the fine cooperation that we received from American physicians that visited Greece. Such fine men as Dr. Leon Unger and Dr. Louis B. Mark took time from their pleasure trips to address groups of Greek physicians on the latest advances in their specialties. It was possible for us to arrange for the meetings and translation services for the speaker. These talks were important supplements to the knowledge of the Greek physicians who heard them and were very greatly appreciated. They continued the good feeling left by the meeting of the World Medical Association in Athens in 1952.

I believe that this important contribution by American physicians should be continued. Before I left Athens, arrangements had been made to provide visiting physicians with all the lecture facilities they may require, including translators and projection of films and slides. Inquiries about these services should be made two months in advance through the American Embassy, Athens, Greece. The Embassy's United States Information Service should be asked to work with Dr. Paul Kapalas of the Greek Ministry of Social Welfare to arrange details of meetings on convenient dates. Dr. Kapalas speaks English and is Director of the Division of Health Education.

WHIPLASH INJURIES OF THE NECK

To the Editor:—The article "Common Whiplash Injuries of the Neck" by Gay and Abbott (*J. A. M. A.* 152:18 [Aug. 29] 1953) is quite timely and excellent; however, certain statements are open to serious challenge. In one place the authors mention cars being ". . . driven ahead several hundred feet by the impact . . ." after being hit in the rear by another car. This is incredible if not ridiculous. If a car were standing on the level without brakes it would take an impact of many hundreds of foot tons to drive even a Ford or Chevrolet "several hundred feet by the impact," and the occupants of such a car would suffer far more than whiplash injuries.

In the illustration on page 1699 on the "mechanics of whiplash injury," the general argument violates basic principles of physics. Position *B* in the illustration is grossly erroneous. Assume that car B strikes car A from the rear. Passengers in car A are motionless in respect to car A. When car B strikes car A in the rear, most of the kinetic energy of car B is transferred to car A in the form of accelerated forward motion. The passenger in car A, by reason of inertia, will tend to remain fixed in space. The net effect is that car A is suddenly propelled forward from under the passenger. The back of the seat forcibly strikes the passenger in the back and carries forward with car A that portion of his body supported by the back of the seat. The head and neck, being unsupported, tend to remain fixed in space so that the body is in effect forcibly driven out from under the head and neck. This is the mechanism of whiplash injury.

Forward flexion of the head and neck can occur only if car A strikes some relatively immobile body ahead and is suddenly decelerated. This is what happens to occupants of car B when it strikes car A. Car A is accelerated; car B is decelerated. Acceleration throws the body backward and causes whiplash injuries; deceleration throws the passenger forward against the instrument panel, etc. Obviously, it often happens—especially in heavy traffic—that a car is accelerated by being struck in the rear and then is decelerated by striking a car ahead. In such a case a person may well sustain a whiplash injury first and then be thrown forward and sustain other injuries. In another place on page 1699 the authors state that "multiple oscillations of the head and neck occurred in alternate flexion and extension." In such collisions the human body is rather inert and has about as much capacity for such "multiple oscillations" as a sack of potatoes. It cannot oscillate like a tuning fork.

For many years I have been increasingly annoyed by the tendency of my confrères to stigmatize as "psychoneurotic" any symptom complex for which an organic cause could not be easily demonstrated. I cannot accept as true the authors' statement that "a persistent psychoneurotic reaction" is responsible for prolonged disability in victims of whiplash injuries. The authors' own statements make this improbable. They mention the probability of various degrees of rupture of intervertebral ligaments and admit that herniated cervical intervertebral disk was clinically diagnosed in 26% of their series.

I have personally observed innumerable automobile collisions ranging from trivial to the severest. For some years I was one of the autopsy surgeons (full time) to the coroner, Los Angeles County, California. I have performed autopsies on quite a number of persons who were killed by the worst of whiplash injuries—"broken neck." I have performed autopsies on at least a dozen persons in whom the skull was completely dislocated from the spine by such injuries. In hospitals I have seen quite a number of very serious but nonfatal fractures of the cervical spine by whiplash injury. Drs. Gay and Abbott describe the less serious, nonfatal whiplash injuries. Even in the less serious whiplash injuries, who can say how much intervertebral ligamentous tearing exists? Who can say how much hemorrhage occurs at the site of the injury and how much subsequent fibrosis and adhesions develop around nerve roots or into or between cervical muscles? Certainly such things may be expected to result in some degree of prolonged or permanent impairment. Even worse, who can say how much or how little trauma of the cervical cord is incurred?

Certainly the x-ray cannot give the answers to these questions. By the same token early treatment and physiotherapy may be expected to minimize sequelae, and delayed treatment can be difficult or futile. Prolonged immobilization—necessary or unnecessary—could be expected to similarly result in prolonged or permanent difficulty not detectable by x-ray.

The neck being a highly mobile structure, it seems reasonable to expect that any post-traumatic fibrosis around nerve roots or into or between muscles, even though rather slight, could be expected to give more prolonged symptoms than elsewhere along the spine. It seems to me that one should be very reluctant to categorically state that "More than half the patients in this series . . . were seriously handicapped in this way," i. e., by "persistent psychoneurotic reactions." Many symptoms are due to real factors that cannot be objectively demonstrated. Not a few persons die of causes that cannot be demonstrated by the most thorough autopsy. Such persons do not die of psychoneuroses.

HYMENOLEPIASIS

To the Editor:—In a report about human hymenolepiasis in The Journal, Sept. 5, 1953, page 47, there is a report of the work of Dr. Dacio F. Amaral of São Paulo, Brazil. It is stated that Dr. Amaral found that chloroquine and gentian violet are not effective against hymenolepiasis due to Hymenolepis nana. After giving two or three courses of chloroquine, I have obtained cures in 40% of patients with this infestation. In spite of this low per cent, chloroquine is superior to other drugs in the treatment of this condition. I usually give 0.01 gm. per pound of body weight (but not more than 0.5 gm.) daily for 25 days. I have also given three tablets containing 0.15 gm. of chloroquine and 0.05 gm. of quinacrine daily to adults for 20 days and one tablet daily for every three years of apparent age to children for 20 days. The rate of cures is the same as for chloroquine alone. Because of the danger of autoreinfestation parents are advised to use the same precautions used to prevent reinfestation with oxyuris. In Cuba, infestation with H. nana is commoner in school age children than in adults.

FREE BALLOON ASCENT

To the Editor:—Our attention has been called to a reference to the National Geographic Society-Army Air Corps stratosphere record achievement, Nov. 11, 1935, in a free balloon ascending to 72,395 ft. from the Stratosphere Bowl near Rapid City, S. D. The two U. S. Army Air Corps balloon experts who achieved this record were Capt. A. W. Stevens and Capt. O. A. Anderson. In The Journal, Oct. 3, page 485, John F. Fulton, M.D., erroneously credits the achievement to the distinguished Swiss scientist Dr. Auguste Piccard.

THE LEISURE CORNER

COOKING FOR PLEASURE

No history of civilization would ever be complete without cognizance of the role played by food as a motivating force behind great events. When primitive man discovered that the flesh of his captures became softer and more palatable after being subjected to the action of fire, the art of cooking began. But, like all the arts, it was tempered by the passage of time and progressed slowly and laboriously from a simple achievement to an elaborate process. Throughout the ages, historical figures who attained victories in the more subtle realms of diplomacy are known to have employed food, sumptuously prepared and served, as a pleasurable weapon in order to add persuasiveness to their arguments. On a more familiar level, food has been used by every clever homemaker for the purpose of enriching the happiness of a home and its inhabitants.

During the past decade or so, the art of cooking has attained new stature in the United States. Through their newly acquired experiences as world travelers, many Americans have learned that distant corners of the world possess fascinating culinary customs of which they were hitherto unaware. One result, of course, has been to remind them that great numbers of Americans have in years gone by cast off old world cooking habits that were once native to their fathers and mothers and grandparents. There has also dawned the realization that many dishes, reintroduced to the palate, would provide plenty of opportunities for a more colorful and satisfying type of living.

The abundance of unusual foods and spices that now flow into the United States from all over the world, together with the vast supply of native-grown food products that is produced by our own diverse climate and frequently refined by elaborate manufacturing processes, tend to make the United States a natural habitat of the connoisseur of fine food. From Spain and Portugal has come a fondness for olives and oil, sharp peppers, and a variety of spices, as well as the custom of frying fish in oil. Sweet-and-sour stews had their origin in Germany, while the tasty contributions of Holland include herring, pickled cucumbers, dainty butter cakes, and coffee cakes. An aggregate of soups, stewed fish, stuffed fish, and sour cream dishes are derived from Poland, and from Russia have come blintzes, different kinds of borsch, *kasha* (a mush of coarse buckwheat, barley, or millet), pickled red cabbage, smoked fish, and fermented dark bread. Hungary contributed paprika and strudel, and Romania many variation for preparing the eggplant. Transplanted to the United States the Smörgåsbord, an old Scandinavian custom, has grown deep roots in our national gastronomic affections until now we feel that it belongs to us. All these gustatory accomplishments, in turn, are complemented by America's own contributions, namely, corn, sweet potatoes, and turkeys, to name an important few. Obviously, all countries have contributed to the advancement of the culinary art, culminating in the United States as a gastronomic melting pot and a desirable eating place for peoples of many religions and folkways.

Today, something new has been added to the age-old saga of good cooking—a growth in the number of persons of both sexes who are interested in good cooking. Since ideas and ideals pertaining to American cooking have their roots in various lands and cultures, a growing pride in the preparation and serving of interesting meals has developed among many American men and women. It is no longer considered chic, charming, or "intellectual" to be ignorant in the kitchen. Many men from all walks of life, including physicians, have taken very much to heart the motto "Every man should learn to cook in self defense." They have learned that if food that is prepared is basically good and if there is contrast in texture, color, and flavor, this will constitute more than half the cooking battle. Add to this the zest of being able to cook an unusual dish or meal, and the amateur male cook is certain to establish an enviable reputation. It is axiomatic that an unusual dish or meal stimulates the appetite by appealing to the eye; so that, if food is properly and tastefully served, it will first gratify the eye, then the nostrils, then the tongue and the palate. The digestive apparatus will do the rest.

To reveal a secret—there is no mystery about cooking. While it is true that the proper preparation and serving of good food is an art that satisfies the inner man and gives pride and pleasure to the cook, cooking, if the truth be known, is not an art that requires special talent. Actually, it is a skill that almost every able-bodied man can readily learn. The warmed-over facts of the matter are that there is no such creature as a natural cook. As any seasoned cook will tell you, "they all have to learn, sooner or later." Although the process may prove painless and training in the kitchen may be absorbed almost unconsciously, every good cook has to be exposed to cooking education of some sort. Some men will take to cooking more easily than others, but, if there is interest in appetizing food and its preparation, then every male physician in the land has the potentialities for becoming a good cook.

At least half of the social and culinary success of any hurried epicurean depends upon a reasonably substantial stock of supplies. The ability of the medical man to whip up something refreshing with miraculous speed and apparent ease frequently depends as much on skill in shopping and management as on skill in cooking. Another point to be emphasized is that the core of all epicurean effort seems to be centered in a treasury of seasonings. The amateur cook will want all that he can find of the usual spices, herbs, and flavorous seeds such as salt, pepper, cloves, cinnamon, allspice, nutmeg, ginger, curry, sage, thyme, rosemary, savory, and paprika. And a few of the less usual ones, too, such as cardamin, cumin, and saffron. Not to be overlooked, however, are condiments, olives, and pickles to be used not only at the table but also in the preparation of food.

Wines can also be used frequently in planning a gastronomic tour de force, table wines, sherry, port, rum, brandy, and an occasional dash of champagne. Wine is exceedingly helpful in glamorizing simple dishes and simple meals. It should be borne in mind that wine provides flavoring, and that flavoring is very often one of the least expensive ingredients of the dish, as well as the most important. Wines employed in cooking need not be expensive, but they should be well flavored and well made. This is also true of other liquors—brandy, rum, liqueurs, and cordials.

For years many persons have felt that the use of rum and brandy for the ever-so-easy, dramatic trick of serving food flambé (afire) should be confined only to Christmas pudding. But a number of famous restaurateurs have popularized food flambé, and now all manners of food ranging from appetizers to soups, meats, fish, puddings, and ices acquire a refreshing attractiveness and a definite mellowing and blending of flavors by the addition of some type of spirits. Finally, the amateur male cook should not serve a dish; he should *present* it to his guests, and the manner of his presentation will prove every bit as important as his preparation. Much of the difference between plain cooking and epicurean cooking is the difference in the way food is served.

The ability of the male amateur cook to cook well is, as has been pointed out, something on which reputation and fame can be built. Perhaps his friends will be amused by his early attempts to master the culinary art, but, if a dish or a meal is tastefully and unusually well prepared, they will turn to applaud with admiration. For bachelor physicians especially, the simple question "What shall we have for dinner tonight?" will provide a new and refreshing invitation to hospitality.

Primary Myocardial Disease in Infancy and Childhood—Rosenbaum and associates observed at the Children's Medical Center in Boston 45 children with severe heart disease of a type that could not be classified as either rheumatic or congenital heart. All children had cardiomegaly and electrocardiographic abnormalities, but the blood pressure was normal and significant murmurs were absent. Twenty-six of the children died, and autopsy studies revealed glycogen-storage disease of the heart in three patients, aberrant left coronary artery in one patient, medial necrosis of the coronary arteries in two patients, idiopathic myocarditis in 10 patients, and subendocardial sclerosis in 10 patients. An attempt was made to establish clinical criteria for the differential diagnosis of these five separate diseases in living patients. All of these patients showed generalized cardiomegaly on x-ray examination, and in the majority left ventricular hypertrophy and T-wave changes of myocardial damage were revealed by electrocardiography. These cases may be divided into two subdivisions. One group includes glycogen-storage disease of the heart, aberrant left coronary artery, and medial necrosis of the coronary arteries. These are rare conditions that are usually seen in infants under 6 months of age and in which congestive heart faliure is uncommon. Idiopathic myocarditis and subendocardial sclerosis constitute the second, and much larger, group. Here the age at onset of symptoms is frequently beyond 6 months, and congestive failure is usually present and often severe. The first group is not amenable to treatment; the second frequently responds to digitalization. Such a division is admittedly not sharp, and there is considerable overlap from one group to the other.

Transposed Pulmonary Veins.—Ten patients (four adults and six children) with transposed pulmonary veins are described. These included four patients with partial and two with complete pulmonary vein transposition, in whom cardiac catheterization and clinical findings are correlated. The remaining four patients presented (1) pulmonary valvular stenosis with partial transposition of the pulmonary veins and intact ventricular septum, (2) a left superior vena cava entering a sinus venosus in common with the hepatic veins and anomalous drainage of the right pulmonary veins into the right atrium, and (3) tricuspid atresia with partial transposition of the pulmonary veins (two cases). The diagnosis of anomalous pulmonary vein drainage was made by cardiac catheterization with roentgen visualization of the catheter in the anomalous vein, by a characteristic pulmonary vein pressure curve, and by 90 to 95% oxygen saturation in the blood sample from the anomalous vein. Surgical exploration was done in the two patients with complete transposition of the pulmonary veins. In both, a left pulmonary vein was anastomosed to the left atrial appendage. In one patient this resulted in definite improvement, while the other died a short time after the operation. Surgical treatment should be reserved for patients with complete transposition accompanied by increasing limitation of physical activity. Usually surgery is not indicated in patients with partial transposition.

Diagnosis of Overriding Aorta.—"Overriding aorta" is an anatomic term indicating that the vessel, at its origin, straddles the interventricular septum and, therefore, accepts blood from both ventricles. A high interventricular septal defect must coexist. Current methods of diagnosing overriding aorta may be divided into the following categories: (1) those involving x-rays, including angiocardiography; (2) studies of the speed of the circulation; (3) methods that depend on the relative saturation of arterial blood with oxygen; and (4) cardiac catheterization studies. Conventional studies involving the speed of the circulation, including angiocardiography, may prove a right to left shunt without indicating its site. Pressure relationships obtained during cardiac catheterization may be relied upon only to exclude overriding aorta. Passage of a catheter into the aorta from the right ventricle is the most reliable method of proving the diagnosis of overriding aorta. A rapid right ventricle to ear circulation time is strongly in favor of this anomaly. In 44 patients, during the course of the routine diagnostic cardiac catheterization, 3 to 5 cc. of a 0.5% solution of Evans blue was injected directly into the right ventricle through the cardiac catheter, and its arrival in the blood vessels of the ear was timed by means of a Millikan oximeter. The possibility of veno-arterial shunting through an interatrial septal defect is eliminated by injecting the dye directly into the right ventricle. In 13 of 44 patients in whom this test was done, overriding aorta was believed to be present. In this group the range of circulation times from the right ventricle to the ear was 3.2 to 13.4 seconds. The authors believe that a circulation time from the right ventricle to the ear of less than 5 seconds is very suggestive of overriding aorta, and a time of 4 seconds or less is almoset certain evidence. A circulation time of more than 5 seconds does not rule out overriding aorta, particularly when the right to left shunt is small. With rare exceptions, the presence of a right-sided aortic arch in a cyanotic patient indicates that the aorta arises as a whole or in part from the right ventricle. A case of a 29-year-old woman is described indicating that the ordinary clinical examinations are sometimes unable to establish or exclude the presence of this condition. In particular, a right to left shunt through an interatrial septal defect may be of such magnitude as to lead to a shortening of the circulation time equal to that caused by an overriding aorta. This may be reflected in early visualization of the aorta during angiocardiography. It is often impossible to ascertain by angiocardiography if premature visualization of the aorta occurs by way of an overriding aorta or via an interatrial septal defect. It is erroneous to assume that overriding of the aorta is present because opacification of that vessel occurs at a time when the left ventricle is not visualized. Ventricles, especially the left, are not usually well seen in angiocardiograms.

Hepatolithiasis.—Hicken and associates present an analytical study of 35 cases of cholelithiasis. They stress that hepatolithiasis is not as rare as is assumed, since, according to one investigator who summarized all reported cases, hepatic calculi occur in approximately 7.4% of cholelithiasis. The fact that intrahepatic and extrahepatic bile ducts form one continuous ductal system affords a rational explanation for the genesis of liver stones. If infected bile, plugs of mucus, biliary sand, and small gallstones are able to float around in the choledochal bile, what is to deny them entrance into the liver radicles? The stagnant bile, which cannot escape from the obstructed choledochus, enters the confluent hepatic ducts. Cholangitis, which often originates in the choledochus, tends to spread upward and to attack the liver radicles. When increased intraductal pressures distend and dilate extrahepatic bile ducts, the same changes are found in the hepatic components. If such pathological soil is capable of producing stones within the large bile ducts, there is no reason to believe that the same would not happen within the hepatic segments. Hepatic calculi were multiple in 95% of the 35 cases observed by the authors. They were found in both lobes of the liver in more than half of the patients. Hepatic calculi do not produce a characteristic clinical syndrome. Occasionally the stones remain silent, but, when they cause disturbances, the resulting symptoms are those of biliary colic. A correct preoperative diagnosis was not made in a single case of this series. The calculi were discovered at surgery by means of operative cholangiography in 51% of the cases and by postoperative cholangiograms in 49%. Awareness on the part of the surgeon is not helpful for detection. Suspicion of hepatic calculi should be aroused, if the extrahepatic ducts contain small stones, biliary sand, or inspissated bile pigments; if one segment of the liver is enlarged, cirrhotic, and bile stained; if there are localized liver abscesses; and if calcified shadows appear on the roentgenograms. Stones residing in the large intrahepatic ducts can often be extracted by instruments, and biliary sand or debris can often be flushed out of the hepatic radicles. The problem of removing multiple calculi seems unsurmountable. Chemical dissolution or fragmentation of the residual stones by irrigating the bile ducts with solvents has been disappointing. Fifteen per cent of the patients in this series required subsequent operations because the hepatic stones descended into the large bile ducts and produced either painful colic or obstructive jaundice.

Phlegmasia Cerulea Dolens Following Injection of Sodium Morrhuate.—The case presented by Nelson concerned a woman, aged 30, whose past history was negative, except for bilateral internal saphenous varicosities progressive over six years. Four days after she had been delivered of her fourth normal infant, bilateral high saphenous ligations were done by her physician. The right side was done first under local anesthesia. All branches were ligated. The sapheno-femoral junction was clearly identified, the vein was ligated at this point, and 5 cc. of a 5% sodium morrhuate solution was injected into the distal segment. The patient almost immediately experienced severe burning pain in the right thigh and leg. The pain was so severe that general anesthesia was induced for high ligation on the opposite (left) side, which was again followed by injection of sodium morrhuate, but no untoward symptoms developed. The right leg and lower two-thirds of the thigh became dusky blue and swollen within two hours. The foot became white and cold. Relief occurred for three or four hours after lumbar sympathetic procaine (Novocaine) block was done on the day following ligation. The patient was referred to the author four days following ligation, when the right foot, leg and thigh were swollen and deeply cyanotic. Lumbar sympathetic block was done on admission with moderate relief, and eight hours later a right lumbar sympathectomy was done. The patient was discharged assuming that there was a possibility of saving the extremity, except the great toe and distal first metatarsal. One month later, when she returned, the dark areas of the leg and thigh were gangrenous but dry, except at the edges where localized infection was present. Débridement of all necrotic areas was done by combining surgical and chemical methods. Later a partially open amputation was done just below the knee. The clinical picture was that of phlegmasia cerulea dolens with associated severe vasospasm and ischemic necrosis. It differs from previously reported cases in that (1) it developed immediately following sodium morrhuate injection of the ligated saphenous vein; (2) it was associated with complete thrombosis of the anterior tibial artery with necrosis of the muscles of the anterior tibial compartment; and (3) it was not associated with deep venous thrombosis. Phlegmasia cerulea dolens is used as a descriptive term for a clinical variant rather than a term for a definite disease entity. The author concludes that in the treatment of varicose veins multiple ligation or stripping is a much more controlled procedure than retrograde injection of an irritant.

Keratosis of Larynx as a Premalignant Lesion.—The lesions of the 125 patients with keratosis of the larynx reviewed in this report were classified clinically into three groups: (1) those that were carcinoma when first seen (57 lesions), (2) those that were first benign and later developed into carcinoma (27 lesions), and (3) those that never showed evidence of malignant degeneration, some after years of observation (41 lesions). This report is concerned chiefly with the 27 patients in whom the lesion was first diagnosed as keratosis and later progressed to carcinoma. Since it is impossible to tell which area will remain keratotic and which will undergo carcinomatous change, the entire keratotic area should be eliminated if possible. In simple keratosis improvement will follow within two or three weeks after the removal of irritation of the larynx. If the lesion does not exhibit evidence of healing within this time, it must be regarded with suspicion. Persistent or recurrent keratosis requires repeated histological study including the subepithelial layer to detect the malignant change. In observing keratosis of the larynx clinically, the authors found that those lesions that exhibited an inflammatory zone around the periphery of the keratosis were more apt to be malignant or undergo malignant degeneration than those around which there was no inflammatory zone. Lesions with an irregular projection above the surface and with a papillary appearance oftener were found to contain carcinoma than those in which the lesion was flat with no sharp line of demarcation between the keratosis and the normal mucosa. In lesions that undergo malignant degeneration the first histological change commonly observed is an alternation in the intraepithelial cellular structure, which is designated as carcinoma in situ. This stage of malignant cellular change limited to the epithelium, and without invasion of the basement membrane, may last for many years, and its potentialities are in doubt. This change may also be the first indication of invasive carcinoma. At times one may find carcinoma in situ adjacent to invasive carcinoma or invasion may be present in other parts of the lesion. Repeated histological examination of different portions of the keratotic lesions may be needed to make an accurate diagnosis. The management depends upon the clinician's evaluation of the lesion. He cannot accept a negative pathological report as unequivocal. The clinical appearance of the lesion and the laryngologist's judgment are important factors in determining the treatment. Irradiation may make the keratotic lesion disappear while it is still in the premalignant stage. In those lesions in which the first manifestation of carcinoma is keratosis, the management is that of a laryngeal malignancy.

Gastric Malignancy.—Of the total of 707 cases of malignant gastric tumors, which Abrahamson cites in this report, 583 had been previously reviewed having been observed at the Bellevue Hospital in New York City between 1919 and 1946. The remaining 124 cases, with which this paper is chiefly concerned, were studied during the last decade at the Stamford Hospital, Stamford, Conn. Comparative studies on this material indicate the poor prognosis of patients with gastric cancer, and emphasize that no real progress is being made and that this is due chiefly to the failure to diagnose gastric cancer early. The cumbersome methods of studying the gastric mucosa are mainly responsible for the fact that many patients who require such studies are not receiving them. Although the gastric cancer was diagnosed roentgenologically in more than 90% of the patients of this series, in many the roentgen examination took place at a stage when the condition was already too far advanced for cure. If gastrointestinal roentgen examinations had been done at an earlier date, the percentage of resectable cases would have been greater. Gastroscopy if carried out by those experienced in the method may prove helpful in questionable cases. Improved methods of examining the gastric mucosa are urgently needed. That delay in treatment contributes to the unfavorable prognosis is indicated by the fact that there was a time lag of four months between diagnosis and operation. The inadequacy of diagnosis is also illustrated by the fact that 37% of the patients had metastases on admission. Since cure by surgery is possible in early local cancers of the stomach, no improvement can be expected until these lesions are brought to operation, while they are locally removable. If the acid content is low and blood cells are found in the gastric contents, the patient should be regarded as having cancer, until proved otherwise. Cytological examination of gastric washings has proved of value only when the findings were positive. Although gastric malignancy requires adequate radical surgery, attempts to prevent regional node metastasis by routine total gastrectomy are not consistent with the anatomic relationships and are not compatible with the best interests of the patient. The prognosis of a patient with carcinoma of the stomach is equally poor in a large teaching hospital in New York City and in a general hospital in a city of 100,000 in Connecticut.

Effects of Corticosterone in Rheumatoid Arthritis.—The administration of corticosterone to one patient with rheumatoid arthritis caused marked sodium and chloride retention but had no antirheumatic effect. The appearance of knee involvement with effusion suggested an actual increase in the activity of the rheumatoid arthritis during treatment with corticosterone. Since the knee effusion continued beyond the period of posttreatment diuresis of sodium, they could not be attributed to sodium retention and probably represented a fluctuation in the natural course of the disease. Thus it would appear that corticosterone had neither a favorable nor unfavorable effect on the arthritis. No significant changes in carbohydrate tolerance or calcium and nitrogen excretion were evident from the administration of this hormone. Although the data indicated potassium retention, it is doubted that it was a definite hormone effect.

Interdependent Effects of Stress and Adrenal Cortex on Carbohydrate Metabolism.—A series of 280 glucose, insulin, and glucose-insulin tolerance tests were performed on 150 normal subjects and 53 patients in order to compare the effects of cortisone on carbohydrate metabolism in the presence and absence of the stress of illness. The observations made are considered to be compatible with the concept that there is an interaction between stress and adrenal hormone in modifying carbohydrate metabolism. They are not reconcilable with the view that the metabolic alterations during stress are direct consequences of adrenal cortical hypersecretion.

Amyotrophic Lateral Sclerosis.—Arnold and associates observed, during a tour of duty on Guam, 50 cases of amyotrophic lateral sclerosis among 25,500 natives. The incidence of one case in each 510 natives appeared unusually high. Information obtained from leading neurologists indicated that incidence of one case to 50,000 persons was an approximate estimate of occurrence of this disease in the United States; thus, the frequency of amyotrophic lateral sclerosis among the natives of Guam was 100 times greater. Consanguinity was definitely not a factor. Many of the natives attributed their affliction to hard work, particularly to forced labor and inadequate diets during the Japanese occupation. Five patients were heavy drinkers of "tuba" made from the coconut; the remainder drank only moderately or not at all. Most of the older natives chewed betel nut, but no apparent relationship has been reported. Three patients recalled a febrile illness suggestive of encephalitis in their youth. None of the patients were affected by the epidemic of Japanese B encephalitis, which occurred on Guam during 1947 and 1948. Autopsy was done in seven, and microscopic examination of the spinal cords and brain stems confirmed the diagnosis of amyotrophic lateral sclerosis. The clinical pictures were classified according to the three groups recently suggested by Swank and Putnam: the complete or Charcot, the atypical, and the incomplete picture. The complete, or Charcot, form of the disease was present in 27 patients who showed amyotrophy, lateral column signs, and muscular fasciculations. Bulbar involvement, which eventually appeared in all patients of this type, ranged from occasional fasciculations and slight atrophy of the tongue to extensive facial wasting, marked atrophy and loss of strength to protrude the tongue, loss of speech, and impairment of swallowing. Eleven of these patients died. In all of the bulbar cases, amyotrophy had become so severe that only fluids could be taken and these with difficulty. Five patients were classified as having the incomplete type, and 18 as having the atypical type. These latter patients showed definite evidence of amyotrophic lateral sclerosis, but the distribution of involvement was unusual.

Surgical Consideration in Focalized Pulmonary Histoplasmosis.—Forsee and associates show that histoplasmosis is a fungus disease often manifested in the lungs. It is rather common in a benign form. Their interest developed as a result of experience in the surgical management of round pulmonary lesions such as tuberculoma and coccidioidoma in an Army hospital. As the focalized pulmonary lesions of histoplasmosis have become recognized, there has been a marked decline in the incidence of pulmonary lesions classified as tuberculoma in which the tubercle bacillus was not demonstrable. The authors have made the diagnosis of focalized pulmonary histoplasmosis in 30 patients following surgical exploration of the hemithorax and histopathological examination of excised pulmonary and mediastinal lesions. The age of the patients ranged from 20 to 48 years, and all but two were men. The authors regard it as noteworthy that 13 of the patients had been in Panama. Symptoms were either mild or absent; 14 of the 30 had no symptoms referable to the chest. In 12, the lesion was noted on a routine chest roentgenogram, and, in two, the discovery was made as a part of a study to ascertain the cause of epigastric distress. Among these, one patient had had roentgenographic evidence of the lesion for seven years, and two patients had had roentgenographic evidence of lesions for four years. Sixteen patients had symptoms referable to the chest, such as hemoptysis, productive cough, chest pain, and moderate loss of weight. The roentgenographic findings were those of any other so-called round or ovoid density within the lung or mediastinum. Sputum smears and cultures of sputum and gastric washings were repeatedly negative for acid-fast bacilli. With the use of the periodic-acid Schiff stain, Histoplasma capsulatum was identified in the excised pulmonary or mediastinal lymph node tissue in all patients. Cultures for H. capsulatum were positive in only one patient. The inability to culture the organisms from the focalized lesions is probably due to their inviability. The surgical excision was accomplished by wedge excision of the lung tissue containing the lesion in 23 patients. Two had lesions excised from more than one lobe, two were treated by segmental resection and two by lobectomy (right middle lobe). The excision of hilar lymph nodes alone led to the diagnosis in three patients. The recognition of histoplasmosis as a granulomatous pulmonary lesion, often focalized and benign, is a further aid in the diagnosis and therapy of the lesions within the lung and mediastinum, the nature of which cannot be ascertained without surgical exploration.

Atrio-Septo-Pexy for Interatrial Septal Defects.—Bailey and associates report that since their first presentation of atrio-septo-pexy for the correction of abnormal interatrial communication considerable additional experience has been gained in surgically treating such patients. While the original basic concept has proved to be sound, certain technical variations have been developed in order to manage the different clinical variants of this situation. The authors discuss the pathological anatomy, course, and prognosis of interatrial communications, explain the principle of atrio-septo-pexy, describe the technique of this method, and present the histories of 21 patients in whom they employed the method. The operation is a relatively simple surgical plastic procedure capable of closing nearly all types of atrial septal communications by bridging the defect with a portion of the invaginated right auricular wall. No significant interference with the flow of vena caval blood need be produced. The auriculoventricular valves need not be disturbed. Should it ever prove necessary to interrupt completely the superior vena caval flow, this can be tolerated if the azygos vein system is preserved intact. Associated lesions, such as coexisting mitral stenosis or anomalous entrance of the right pulmonary veins into the right atrium and/or superior vena cava, can and should be corrected at the time of closure of the defect. Coexisting total transposition of all pulmonary venous return probably requires a two-stage surgical procedure for its correction. Very low defects, such as persistent ostium primum, may require the addition of anterior-posterior approximating atrial mattress sutures, after the method of Murray. Great defects, such as single atrium, may be improved or corrected by a modification of Murray's technique. To date, the results obtained in correcting defects of the septum secundum have been reasonably satisfactory. Two deaths occurred in 14 patients with septum secundum defects. Clinical improvement was observed in all the survivors. In seven patients with persistent ostium primum, complete closure of the defect was accomplished in four instances. Three of the seven patients died, apparently as a result of unrelated factors, hypothermic depression of the myocardium, renal shutdown, and very poor condition. The surgical measure, itself, should not entail a great mortality.

*Primary Pulmonary Sarcoidosis: II. Clinical Course and Prognosis. S. Löfgren.—p. 465.

Primary Pulmonary Sarcoidosis.—The initial symptoms of primary pulmonary sarcoidosis were studied in 161 women and 51 men with bilateral hilar lymphoma syndrome, the most important feature of the primary stage of sarcoidosis. The term "lymph node stage" is, therefore, suggested for the initial stage. In 78 patients (37%) the paratracheal lymph nodes were also involved, usually on the right side, rarely on both sides, and in no instance on the left side alone. In 28 patients (13%) parenchymal lesions were also observed when the diagnosis was made. Erythema nodosum occurred in 107 women and 6 men. In this group of patients the incidence of fever, increased sedimentation rate, and articular symptoms, particularly of the ankles, was so high that these symptoms must be considered as typical. In 38 women and 32 men, sarcoidosis was detected on routine roentgen examination of the lungs. As a rule, these patients felt entirely comfortable and had a normal or only slightly increased sedimentation rate. There was an intermediate group of 29 patients in whom erythema nodosum was not present and in whom hilar lymphomas were observed on roentgen examination carried out because of other symptoms, such as cough, dyspnea, joint pain, or fever. The group of patients with erythema nodosum presented fairly consistently the acute stage of the disease and offered the best opportunity for studying the clinical aspect of primary sarcoidosis. The onset of the disease in patients belonging to the two other groups is more difficult to ascertain and these groups must be expected to comprise a certain number of cases more chronic in character. Patients were followed up from 2 to 16 years. In addition to the 28 patients with parenchymal lesions at the time the diagnosis was made, such lesions developed in 53 during the subsequent course of the disease. Of these 81 patients, shotty ("miliary") lesions were observed in 20, reticular in 22, a combination of these two types in 29, and patchy or coalescent lesions in 10. Of 111 patients with erythema nodosum who were available for follow-up examinations, 71 (64%) showed complete regression of both the lymphomas and the parenchymal lesions within one year and 102 (91.9%) within two years. In only nine patients (8.1%) was a chronic trend observed. For the two other groups of patients the prognosis was significantly poorer, probably because these groups comprised cases already in the chronic stage when the condition was recognized. Thus among 62 patients wtih bilateral hilar lymphomas detected on routine roentgen examination and who were followed up, 45 (72.6%) had a complete regression within two years and 17 showed a chronic trend; of 28 patients of the third group who were followed up, 20 (71.4%) had a complete regression within two years and 8 (28.6%) showed a chronic trend. Only one of all the patients with complete regression had a relapse. Tuberculosis supervened in only one of the 212 patients. Exudative pleurisy was never observed. Extrapulmonary manifestations of sarcoidosis were noted in only 26 (12%) of the 212 patients, but the real incidence of such lesions is probably higher. Except for the 13 patients with uveoparotitis 6 of whom showed a chronic trend, the extrapulmonary manifestations were generally mild and transient. In six patients with cutaneous or subcutaneous sarcoids that developed in old scars from accidents or operations the role of the traumatic factor in the causation of sarcoidotic manifestations was suggested.

Regional Enteritis.—Suermondt points out that lesions in the condition, which Crohn designated as terminal ileitis, are not necessarily limited to this region and, so, prefers the term "regional" to terminal ileitis. Reviewing previous reports and his own observations on 18 patients, he feels that the following factors are important in regional enteritis: 1. Regardless of the location, edema of a circumscribed part of the intestine and the mesentery is a characteristic symptom and an integral part of the morbid process, at least in the initial stages. Later stages are dominated by cellular infiltration of the tissues. 2. The disease is not caused by a specific inflammation. Only normal intestinal flora is found. There must, therefore, be a factor that enables the intestinal flora to infect a circumscribed part of the intestine. 3. Appendicitis plays no part in the etiology. 4. Regional ileitis may disappear spontaneously. 5. There are cases of recurrent attacks of abdominal pain and diarrhea, which develop into chronic regional enteritis, a process that requires surgical treatment. 6. Chronic regional enteritis is predominantly localized in the ileocecal part of the intestine (terminal ileitis in some 80% of cases). 7. Radical resection does not guarantee a definite cure. A relapse may occur several years after operation. The author explains why he regards allergic reactions as the primary cause of regional ileitis and shows that an allergic origin is in accordance with the seven points. The constantly repeated allergen-antibody reaction gives rise to allergic reactions in a circumscribed part of the intestine; this causes circulatory disturbances in the intestinal wall and angioneurotic edema, which results in constriction of the intestinal lumen and stagnation of the intestinal contents. As a result of the combination of these factors, the normal intestinal flora may secondarily cause an infection of this part of the intestine, which in turn gives rise to the clinical symptoms of regional enteritis. If possible, clinical and radiological diagnosis should be followed by radical resection. This technique should be preferred to enteroanastomosis—an intervention resorted to in cases in which resection is not feasible. The prognosis is not favorable, because new allergic reactions may give rise to relapses. In case of relapse, antihistamines can be given to prevent allergic reactions and antibiotics and sulfonamides to control the infection. An elimination diet is also advisable.

*Endangiitis Obliterans Associated with Simultaneously Occurring Necroses of All Four Extremities as Allergical Reaction to Treatment with Penicillin and Sulfonamide. M. A. Schmid.—p. 463.

Intravenous Infusion of Blood Proteins of Cattle in Man.—"Adaequan," a proprietary blood substitute protein preparation obtained from the blood of cattle, was given a therapeutic trial by intravenous infusion to 20 patients who had major operations on the abdomen or thorax. The blood protein levels of these patients were determined, before and after the administration of the preparation, by electrophoresis and balance computation with food tables and determination of nitrogen in the urine. Anaphylaxis did not result from the administration of Adaequan on repeated administration of 250 cc. of the preparation in one series or when the injections were repeated after a three to six weeks' interval. Four patients were given cattle plasma four to five weeks after the administration of Adaequan without untoward reactions. Adaequan, which, according to the information obtained from the manufacturing firm, consists predominantly of albumin and only small additional amounts of globulin, proved to have considerable oncotic activity and consequently may be recommended for patients who require restoration of the fluid reserve. A mild increase in the nitrogen elimination in the urine occurring in the first three days after the administration of Adaequan was considered as a manifestation of the gradual breaking up of the transmitted albuminous bodies. No conclusions could be drawn concerning the biological utilization of the animal proteins. None of the patients showed kidney impairment for which the protein foreign to the species could have been responsible. The results suggest that animal plasma, provided that it had been adequately prepared, may be used as a blood substitute for direct intravenous infusion in man.

Endangiitis Obliterans as Drug Allergy.—Endangiitis obliterans with simultaneous involvement of all four extremities and concomitant necrosis of all phalanges is reported in a 57-year-old man. The general consensus is that endangiitis obliterans is caused by a change in the reactivity of the vessels and the nervous system of the vessels to the allergic-hyperergic side. The author's patient had a congenital as well as an acquired tendency to allergic reactions, since his father had had hay fever and gout and the patient himself had had syphilis. He also had a blood sugar level of 130 to 160 mg. per 100 cc. and hypertension up to 225/130 mm. Hg. Shortly before the onset of the endangiitic manifestations he had an acute catarrhal infection and inflammation of the middle ear, two diseases that are well known to be capable of rapidly changing the condition of reactivity of an organism. For these diseases, the patient was given sulfamethazine and repository penicillin. Within a few days of this treatment, there developed, in both hands and legs of the patient, sudden disturbances in circulation manifested by blue-red spots; pain followed; and the hands and feet became insensitive. These changes increased rapidly and resulted in ulceration on the right foot and in disturbances of cerebral circulation manifested by an occasional diplopia and loss of memory. The simultaneous occurrence of these phenomena while sulfonamides and penicillin were being given was too obvious to be considered accidental. A cause and effect relationship between the endangiitis obliterans and the chemotherapy must be assumed. The assumption was proved by the fact that the patient's condition became suddenly worse when he was given another brand of penicillin three months after the first treatment with this antibiotic. Four days after discontinuation of the drug, the general condition of the patient improved and the necrosis of the fingers and toes, which progressed rapidly in the course of the treatment, was arrested. The positive results the patient had from three intracutaneous tests with penicillin and sulfamethazine furnished additional proof for the cause and effect relationship. The author cautions against the uncritical use of sulfonamides and penicillin.

Tuberculosis in the Shoemaking Industry.—Investigations in shoe factories in England suggested that "shoemakers' phthisis" was not an industrial disease, but merely an example of the sequence of events frequently associated with a laissez-faire policy toward the employment of tuberculous persons in industry. The relative excess of tuberculosis in the boot and shoe industry seems to be due to the presence of an exceptionally large number of tuberculosis carriers in the working population; the unequal distribution of cases within the industry is due to the fact that in large workshops the spread of infection from carriers to fellow workers is greater than in small ones. Since shoemaking is, for men, a relatively light occupation, the industry probably recruits more persons with established tuberculosis than most industries. For the same reason it probably permits men in whom the disease develops on the job to remain at work much longer than if the work were excessively strenuous. In this way, the carrier rate is still further augmented. Provided men with chronic phthisis work on their own, as do most shoe repairers, their presence causes no further harm to the industry as such. But if, as in the case of boot and shoe factory workers, they work in large groups, the disease spreads to others.

Chorioangioma: Benign Tumor of the Placenta.—Many of the complications of pregnancy and many neonatal malformations formerly believed to be caused by the presence of a placental chorioangioma can now be explained by such phenomena as maternal isoimmunization. Prognosis is considered favorable for both mother and child, and no difficulty need be anticipated unless, as seldom happens, the tumor is so large that it causes dystocia or unless hydramnios leads to a premature interruption of the pregnancy. The difficulty of discovering small, deeply embedded tumors and diagnostic errors made in classifying placental chorioangiomas, which vary widely in histological type, have led to estimates of their frequency ranging from 1 in 700 to 1 in 9,000. Rapidly developing hydramnios and delivery of a premature (seven months) infant led to the discovery of a chorioangioma weighing 102 gm. on the maternal aspect of the placenta in a 32-year-old patient, para 3, whose two previous pregnancies had proceeded normally. The postpartum period was uneventful except for a moderate subinvolution of the uterus, and the infant's growth has been normal.

Transfusion Complications Resulting from Toxins in Stored Blood.—Heilmeyer and associates first cite previous American and German reports on bacterial contaminants in transfused blood and the resulting serious complications including deaths. The organisms found in the blood in cases reported in the American literature were usually gram-negative organisms, whereas in the German reports gram-positive organisms were mentioned. Peripheral vascular collapse was the dominating clinical picture. Before presenting three cases of transfusion complications observed at their own clinic in Freiburg, the authors describe the procedure followed in storing blood in bottles and also the apparatus used for transfusion. The first of the three reported cases terminated in death. Subsequent examination of the stored blood was possible only in the first case. In the first case serologic incompatibility between the infused blood and that of the recipient could be ruled out by several tests, but bacteriological examination of the blood remaining in the bottle revealed gram-positive cocci. Blood group incompatibilities could also be ruled out in the other two patients with transfusion reactions. One of the authors searched for and found so-called "early" and "late" toxins in stored human blood. In discussing earlier reports on these toxins the authors say that the main problem, the pathogenesis of such toxins, has not been fully explained. Apathogenic organisms were found, but it was demonstrated experimentally that "early toxin" could be produced in plasma by enzymatic hydrolysis. It is assumed that "early toxin" is a product of protein decomposition. Such protein cleavage could be induced by substances in the blood itself, by substances that have been added, or by microorganisms, even if they are nonpathogenic. The authors do not mean to imply that "early toxin" is the only toxin that can produce shock after infusion of stored blood. They point out that histamine has been found in dried human plasma, and that, in dried serum, another, as yet unidentified substance, has been found. The authors emphasize that, even though careful matching of bloods has been carried out, the complications induced by mechanisms discussed in this report may be more frequent than those caused by blood group incompatibilities. They question the value of a proposed German law on blood donorship that disregards these factors.

Spinal Compression Due to Skeletal Fluorosis.—An earlier study on the distribution of fluorine in the waters of the Visakhapatnam district indicated that this region gave abundant opportunities for the study of endemic fluorosis. The history of a patient with advanced skeletal fluorosis is presented. The diagnosis was supported by signs of mottled enamel, osseous changes, such as exostoses and increased density of bones, high urinary excretion of fluoride, and the fact that the water in the village in which the patient had lived contained large quantities of fluorine. When the patient was hospitalized, there was tingling and numbness all over the body and inability to use the lower limbs. The present illness commenced six months prior to admission. The patient belonged to a poor family residing in the village Rolugunta in the Visakhapatnam district. He had a brother and an uncle who had stiff backs; his two children had mottling of teeth, which was quite prevalent among children in the locality. Motor power was poor in all four limbs, but definitely worse in the lower limbs. The gait was spastic-ataxic. These and other neurological changes were the result of compression of the spinal cord and nerves due to abnormal calcification and densification, which could be attributed to protracted ingestion of large amounts of fluorine in drinking water. This was the first case on record in this locality in which fluorosis gave rise to spinal compression. Investigation of the fluorine content of the different wells in the patient's home village suggested that skeletal impairment described as "stiff back" is found to be associated with consumption of water containing 10 ppm of fluorine. Fluorine concentration up to 4 ppm in domestic waters does not seem to constitute such a grave hazard.

Chemotherapy of Pulmonary Tuberculosis.—A year's trial was carried out on the action of isoniazid alone, isoniazid and streptomycin, and *p*-aminosalicylic acid and streptomycin in 68 patients with chronic pulmonary tuberculosis, most of whom had extensive and irreparable lung lesions. Twelve patients received 250 mg. of isoniazid daily for 18 weeks, and 11 were given 250 mg. of isoniazid daily and 1 gm. of streptomycin sulfate six times a week for 18 weeks. Both groups received a second course of treatment. Nine patients received 250 mg. of isoniazid daily and 1 gm. of streptomycin sulfate six times a week for 25 weeks, and nine other patients received 1 gm. of streptomycin sulfate six times a week and 10 gm. of *p*-aminosalicylic acid daily. A group of 13 patients received isoniazid, *p*-aminosalicylic acid, and streptomycin simultaneously, and the remaining patients a different combination of two of these drugs each month. Results confirmed that isoniazid alone has no place in the treatment of chronic pulmonary tuberculosis but that isoniazid and streptomycin given together have a definite therapeutic effect. Relapses after treatment with isoniazid and streptomycin were common, but retreatment with the same drugs appeared fully effective.

Bacteriological Control of Therapeutic Trials in Tuberculosis.—Specimens of sputum from the 68 patients with chronic pulmonary tuberculosis reported on in the same journal by Joiner and associates were examined by microscopy and culture. As long as the patients were receiving treatment, at least three specimens from each patient were examined each alternate week. The bacteriological results indicated that direct microscopic examination of the sputum is probably the most useful laboratory guide to response to chemotherapy, provided a rigid counting technique is maintained. The more frequent the observations (the number of specimens examined for each reading; for example, one, two, or three specimens per week), the smaller was the proportion of patients observed to be sputum-negative over a given period. The fewer the examinations, the greater was the apparent response to chemotherapy. The number of observations and spacing of readings are, therefore, factors of great importance in assessing the response of patients to chemotherapy. The success rate for culture of specimens that were positive on direct microscopy from patients on treatment (73%) was considerably lower than that from patients not receiving treatment (91%). Three possible causes are suggested. (1) the patients may be excreting bacilli which are already dead, (2) the concentration method may be the final insult to organisms already attacked by the drugs in use, and (3) it is possible that, despite washing, enough drug may be adsorbed on the bacterial cells to inhibit growth. The culture of isoniazid-resistant strains of Mycobacterium tuberculosis presented peculiar difficulties. The authors' experiments supported Fisher's view that resistant strains were dependent on a factor present in fraction V bovine albumin, but absent in crystalline albumin. The methods used at present for determining isoniazid sensitivities are unsatisfactory because they are time-consuming, not always accurate, and too slow in yielding results of value in the routine control of treatment. The authors' experience suggests that direct microscopic counts give a more rapid and sensitive index of progress and one of greater practical value.

Active Immunization Against Tetanus.—North and Patterson cite experiences among British, Canadian, and American troops, who had been immunized against tetanus, and among German and Japanese troops, who had not been immunized, as overwhelming evidence in favor of immunization. A conservative estimate of the serum antibody level necessary to give protection against tetanus may be taken as 0.1 to 0.2 unit per milliliter. Such a level has been found in the blood of subjects up to at least nine years after an adequate initial immunization, which includes a "routine stimulating" infection of toxoid after 12 months. The authors feel that, on the evidence presented in this paper, the following principles should be accepted regarding active immunization in civilian practice: 1. A basic course of three injections of fluid toxoid or of two injections of a toxoid containing a mineral carrier should be given. 2. These injections should be followed by a "routine stimulating" injection of toxoid about 12 months later. 3. No further "stimulating" (booster) dose of toxoid should be necessary for at least five years except in the event of injury. 4. After minor injuries the patient should immediately receive an "emergency booster" dose of toxoid if the injury occurs six months or more after completion of the basic course or six months or more after a "stimulating" dose. 5. In the case of severe wounds, especially those of the deep penetrating type, and when there is severe shock, both toxoid and antitoxin should be given immediately in separate syringes and at separate sites. 6. If there is any doubt as to whether a patient has been adequately actively immunized, antitoxin should always be given. 7. When a person has been actively immunized against tetanus, he (or the guardian in the case of a child) should be given a certificate to that effect.

Rheumatic Cardiopathy and Cor Pulmonale.—Observations on 630 patients with rheumatic cardiopathy who were treated in the cardiology center of Buenos Aires during a period of years are reported. Chronic cor pulmonale was observed in 24 (3.8%) patients: in 17 out of 77 with mitral stenosis (22%), in 5 out of 163 with double mitral lesions (3%), in 1 out of 22 with tricuspid and mitral lesions (4%), and in 1 out of 17 with tricuspid, aortic, and mitral lesions (6%). Patients with mitral insufficiency, pure aortic lesions, and combined mitral and aortic lesions did not show the coexistence of cor pulmonale. The authors believe that there is a correlation between mitral stenosis and cor pulmonale from overloading of the right ventricle. An early diagnosis of mitral stenosis of rheumatic origin is of importance for selecting patients for surgical intervention, at a time in which the hemodynamic conditions are still reversible. In advanced cases, surgical intervention is of no avail, since definite anatomic changes have already occurred, through which pulmonary hypertension and the consequent overload of the right ventricle are maintained.

Treatment of Hepatitis by Intervention on Sympathetic Nerves.—Experiments on dogs revealed that bilateral sympathetic nerve block is the best treatment for acute pancreatitis, and bilateral splanchnicectomy for chronic pancreatitis. After acute pancreatitis was produced in eight dogs, bilateral splanchnicectomy was performed in three of them (one had died) one, three, and six hours, respectively, after onset of the disease. The sympathetic nerve was blocked in the other four dogs by injecting 80 to 100 cc. of 0.5% procaine bilaterally into the paravertebral area between the seventh thoracic and the second lumbar vertebrae every six hours by the posterior route. The animals were killed 24 hours after the interventions. Two other dogs that were kept as controls died 8 and 15 hours, respectively, after the disease had developed. Chronic pancreatitis was produced in seven dogs, and they were given a normal diet (milk, meat, and bread) for the entire period of the experiment. Thirty days after the onset of the disease, bilateral splanchnicectomy was performed in three of these dogs, while the sympathetic nerves were blocked in the other four as in the dogs of the first group. The blocking was repeated every day for 30 days, and all the dogs were killed 30 to 40 days after the onset of the disease. Macroscopic and microscopic examinations revealed that bilateral sympathetic nerve block had good effects on the dogs with acute pancreatitis. Clinically, pain and anguish disappeared, the circulation improved, and urination became more profuse; histologically, the intraparenchymatous alterations were restored to normal. This may be ascribed to a temporary inhibiting action of the anesthetic on the neurohormonal activity of the gland and to the improved arteriocapillary circulation. The same method had no effect, however, on the dogs with chronic pancreatitis; their clinical and histological picture remained unchanged. Bilateral splanchnicectomy impaired the pancreatic function in the dogs with acute pancreatitis, but gave good results in the dogs with chronic pancreatitis. It restored to normal the function and structure of the acini and the parenchyma that had been partly destroyed.

Thorn's Test in Postoperative Patients.—Thorn's test was performed repeatedly in patients who had undergone surgery for severe lesions of the stomach, abdomen, thorax, and lower extremities. The circulating eosinophils were counted immediately before the intervention, 1 and 24 hours after the intervention, on the third postoperative day, and every three days thereafter to the 10th day. The number of eosinophils dropped in all patients one hour after the operation. There was always a ratio between the eosinopenia and the type of intervention regardless of the age and sex of the patient. The eosinopenia was always severest on the first postoperative day and lasted for from four to seven days. After that time the number of eosinophils increased abruptly and became greater than the initial values in some instances. Disturbances and complications occurring postoperatively affected the number of circulating eosinophils. Since the results of Thorn's test indicate the way in which patients react to surgical interventions, it may become a good adjuvant in the diagnosis and prognosis of postoperative states.

Respiratory Dead Space and Alveolar Clearance. P. H. Rossier, A. Bühlmann and H. R. Müller.—p. 577.

Serologic Diagnosis of Human Brucellosis.—Ordinary agglutination for brucellosis antibodies may fail even when brucellosis is strongly suspected. Additional diagnostic procedures, such as complement fixation and skin tests are employed, the more so since blood cultures for Brucella organisms largely depend on accidents. Three serologic tests were used in 219 patients with brucellosis studied at the clinic in Zurich. They were the agglutination test (Widal-Wright reaction), the blocking test, and the modified Coombs test. In 18 of these 219 patients, prozones were detected. Since prozones represent specific phenomena of immunity they are particularly important since they make possible a serologic diagnosis of brucellosis in cases in which the ordinary Widal-Wright reaction is negative. For this reason it is advisable to begin with serum solutions of one-fourth or one-fifth because prozones usually appear only in these low solutions. The Widal-Wright reaction would have been regarded as negative in these cases, because, when it is performed, dilution is usually begun at 1:20, and only a positive agglutination at 1:80 or 1:100 is regarded as diagnostic in human serum. The presence of prozones permits a positive serologic diagnosis. The 219 serums included also 19 in which the Widal-Wright reaction was negative up to 1:1,280, whereas the blocking and Coombs tests were positive 18 times and the Coombs test was positive alone in the 19th case. The authors describe the principle of the blocking test and of the modified Coombs test and stress that the serum of patients in whom brucellosis is suspected should be examined for blocking antibodies with either the blocking test and/or the modified Coombs test.

Periarteritis Nodosa.—Fahrländer points out that periarteritis nodosa is classified with the diseases of the connective tissue apparatus, which are also designated as collagen diseases. This concept does not imply that the diseases belonging to this group are all elicited by a hyperergic process. The large majority of cases of periarteritis are not allergic, and they are rarely primary diseases. They frequently begin with an infection of the upper air passages that is followed after an interval of time by a periarteritic process. In addition to general symptoms, such as anorexia, fever, leukocytosis, and prostration, there are manifestations that depend on the organs involved. The kidneys, pancreas, urogenital system, and spleen are nearly always involved and the skin, muscles, and joints, frequently. Besides skin changes, symptoms involving the peripheral nervous system often facilitate the diagnosis. The author presents three cases of periarteritis nodosa that were treated with corticotropin. One of these cases was verified by autopsy and the other two by biopsy. In the first patient, in whom the periarteritis nodosa involved skin, peripheral nerves, kidneys, and possibly the mesenteric vessels, an attack of bronchial asthma preceded the periarteritis. Treatment with corticotropin resulted in a reduction of fever and eosinophilia, but there was no improvement in the neuritis. A new attack involved the pleura. The arteritic process apparently was not influenced by the corticotropin. In the second patient, polyarthritis and multiple subcutaneous nodules developed, but neither renal changes nor hypertension were observed. The temperature was constantly elevated. Under the influence of corticotropin therapy, fever and articular symptoms subsided, the general condition improved, but the cutaneous eruption disappeared only partly, and new attacks followed. In the third patient, the periarteritic changes followed an infection of the upper respiratory passages. Despite treatment with corticotropin, the process progressed in the vasa nervorum and in the subcutaneous tissues as well as in the choroid. The presumably periarteritic changes in the lungs disappeared under the influence of corticotropin. That the adrenal cortex responded to the hypophysial hormone is proved by the complete disappearance of the eosinophils from the circulating blood. These cases contribute nothing to the still unsolved problem of the etiology of periarteritis nodosa. Classification into allergic and hypertensive symptoms applied only to case 1, which began with bronchial asthma, but in this case as in the others hypertension was absent at the beginning of the disorder. In the third case hypertension did develop, but only late, as a sequel of serious renal damage. Only some of the symptoms responded to treatment with corticotropin, and all patients experienced new attacks, thus there was no curative effect.

Prognosis of Contralateral Lung After Resection.—The records of 101 patients who had survived more than three months after pulmonary resection for tuberculosis were studied. The aim was to elucidate factors leading to later deterioration in the contralateral lung. Deterioration occurred in 11 of 101 patients. It was more frequent with disease of recent origin in the contralateral lung. No evidence was discovered that indicated that the extent of disease in the resected lung or length of history had any appreciable influence. If deterioration is to take place, it is probable that it will occur within the 12 months following the operation.

Blood Supply of Malignant Pulmonary Neoplasms.—Cudkowicz and Armstrong examined the bronchial arteries of patients with malignant neoplasms with the aid of an injection of a radiopaque material. A diffuse proliferative bronchial arterial pattern extending to the tumors was demonstrable in four cases.

tions, the greater was the apparent response to chemotherapy. The number of observations and spacing of readings are, therefore, factors of great importance in assessing the response of patients to chemotherapy. The success rate for culture of specimens that were positive on direct microscopy from patients on treatment (73%) was considerably lower than that from patients not receiving treatment (91%). Therapy of Perforated Ulcers of Duodenum and Stomach. P. Häberlin. —p. 571.
*Experiences with Serologic Diagnoses of Human Brucellosis by the Blocking and Coombs Tests. H. Fey and F. Bürki.—p. 573.
*Periarteritis Nodosa. H. Fahrländer.—p. 575.
Respiratory Dead Space and Alveolar Clearance. P. H. Rossier, A. Bühlmann and H. R. Müller.—p. 577.

Serologic Diagnosis of Human Brucellosis.—Ordinary agglutination for brucellosis antibodies may fail even when brucellosis is strongly suspected. Additional diagnostic procedures, such as complement fixation and skin tests are employed, the more so since blood cultures for Brucella organisms largely depend on accidents. Three serologic tests were used in 219 patients with brucellosis studied at the clinic in Zurich. They were the agglutination test (Widal-Wright reaction), the blocking test, and the modified Coombs test. In 18 of these 219 patients, prozones were detected. Since prozones represent specific phenomena of immunity they are particularly important since they make possible a serologic diagnosis of brucellosis in cases in which the ordinary Widal-Wright reaction is negative. For this reason it is advisable to begin with serum solutions of one-fourth or one-fifth because prozones usually appear only in these low solutions. The Widal-Wright reaction would have been regarded as negative in these cases, because, when it is performed, dilution is usually begun at 1:20, and only a positive agglutination at 1:80 or 1:100 is regarded as diagnostic in human serum. The presence of prozones permits a positive serologic diagnosis. The 219 serums included also 19 in which the Widal-Wright reaction was negative up to 1:1,280, whereas the blocking and Coombs tests were positive 18 times and the Coombs test was positive alone in the 19th case. The authors describe the principle of the blocking test and of the modified Coombs test and stress that the serum of patients in whom brucellosis is suspected should be examined for blocking antibodies with either the blocking test and/or the modified Coombs test.

Periarteritis Nodosa.—Fahrländer points out that periarteritis nodosa is classified with the diseases of the connective tissue apparatus, which are also designated as collagen diseases. This concept does not imply that the diseases belonging to this group are all elicited by a hyperergic process. The large majority of cases of periarteritis are not allergic, and they are rarely primary diseases. They frequently begin with an infection of the upper air passages that is followed after an interval of time by a periarteritic process. In addition to general symptoms, such as anorexia, fever, leukocytosis, and prostration, there are manifestations that depend on the organs involved. The kidneys, pancreas, urogenital system, and spleen are nearly always involved and the skin, muscles, and joints, frequently. Besides skin changes, symptoms involving the peripheral nervous system often facilitate the diagnosis. The author presents three cases of periarteritis nodosa that were treated with corticotropin. One of these cases was verified by autopsy and the other two by biopsy. In the first patient, in whom the periarteritis nodosa involved skin, peripheral nerves, kidneys, and possibly the mesenteric vessels, an attack of bronchial asthma preceded the periarteritis. Treatment with corticotropin resulted in a reduction of fever and eosinophilia, but there was no improvement in the neuritis. A new attack involved the pleura. The arteritic process apparently was not influenced by the corticotropin. In the second patient, polyarthritis and multiple subcutaneous nodules developed, but neither renal changes nor hypertension were observed. The temperature was constantly elevated. Under the influence of corticotropin therapy, fever and articular symptoms subsided, the general condition improved, but the cutaneous eruption disappeared only partly, and new attacks followed. In the third patient, the periarteritic changes followed an infection of the upper respiratory passages. Despite treatment with corticotropin, the process progressed in the vasa nervorum and in the subcutaneous tissues as well as in the choroid. The presumably periarteritic changes in the lungs disappeared under the influence of corticotropin. That the adrenal cortex responded to the hypophysial hormone is proved by the complete disappearance of the eosinophils from the circulating blood. These cases contribute nothing to the still unsolved problem of the etiology of periarteritis nodosa. Classification into allergic and hypertensive symptoms applied only to case 1, which began with bronchial asthma, but in this case as in the others hypertension was absent at the beginning of the disorder. In the third case hypertension did develop, but only late, as a sequel of serious renal damage. Only some of the symptoms responded to treatment with corticotropin, and all patients experienced new attacks, thus there was no curative effect.

Case of Retrosternal Diaphragmatic Hernia. R. Warwick-Brown.—p. 162.
Haemoptysis as an Indication for Bronchoscopy. S. J. MacHale.—p. 164.

Prognosis of Contralateral Lung After Resection.—The records of 101 patients who had survived more than three months after pulmonary resection for tuberculosis were studied. The aim was to elucidate factors leading to later deterioration in the contralateral lung. Deterioration occurred in 11 of 101 patients. It was more frequent with disease of recent origin in the contralateral lung. No evidence was discovered that indicated that the extent of disease in the resected lung or length of history had any appreciable influence. If deterioration is to take place, it is probable that it will occur within the 12 months following the operation.

Blood Supply of Malignant Pulmonary Neoplasms.—Cudkowicz and Armstrong examined the bronchial arteries of patients with malignant neoplasms with the aid of an injection of a radiopaque material. A diffuse proliferative bronchial arterial pattern extending to the tumors was demonstrable in four cases of bronchial carcinoma. Large dilated lacunae derived from the bronchial arteries were seen in the tumors. No corresponding changes in the bronchial arteries were observed in two cases of metastatic lung tumor. This evidence supports the observations by Wood and Miller in 1938, when they found proliferative changes in the bronchial arteries only in primary bronchial tumors. Their contention that hemoptysis comes from the bronchial arteries may well be true in view of the large and thin-walled lacunae in the tumor substance that, in the lesions described here, were in continuity with enlarged bronchial arteries. Presumably the pressure in these dilated vascular channels must be high and would exceed the pressure in similar blood spaces derived from the pulmonary arteries. The association of hypertrophic pulmonary osteoarthropathy with bronchial carcinoma is well recognized, and it is of interest that in two of the cases observed by the authors, in which clubbing was prominent, thrombosis and recanalization of pulmonary artery branches by the vasa vasorum of the bronchial circulation could be demonstrated.

*Epilepsy and Its Medical Treatment. M. A. Lennox.—p. 965.
*Significance of Electroencephalography in Diagnosis of Epilepsy. F. Buchthal.—p. 972.
Review of Pathophysiology and Treatment of Myasthenia. L. Engbaek.—p. 984.
Antiepileptics. Brief Review. H. Simonsen.—p. 986.

Epilepsy and Its Medical Treatment.—Lennox considers the medical treatment of epilepsy a trial of patience. It takes time to establish the suitable medication for a patient, and one's inventiveness must never fail. Three simple rules if followed increase the therapeutic success. The first rule is to determine the type of attack and apply the corresponding medication. The special diagnostic difficulty here lies in differentiation between petit mal and psychomotor attacks of brief duration or focal attacks. The second rule is to give adequate doses, i. e., to increase the dose slowly until the attacks are under control or signs of toxic effects appear. The third rule is to change medication or to use a combination of different substances, if the attacks cannot be controlled by sufficient doses of one substance. This should always be done gradually. The most important agents available for treatment of grand mal are, in the order of their reliability and effectiveness, diphenylhydantoin (Difhydan), phenobarbital (Phenemal), and Mesantoin (3-methyl-5,5-phenylethyl hydantoin). The two main agents available for treatment of petit mal, akinetic, and myoclonic attacks are trimethadione (Tridione) and paramethadione (Paradione). Some patients become free from attacks with the one and not the other; paramethadione is less likely to aggravate a simultaneous grand mal. A combination of grand mal and petit mal in the same patient complicates the therapeutic problem; in such cases it is necessary to combine various substances. Expressed in figures, about half of all patients with epilepsy can be made free from attacks, and another 25% can be materially improved. The aim of treatment in epilepsy is control of the seizures together with assistance to the patient in his adjustment on social, economic, and educational levels.

Significance of Electroencephalography in Diagnosis of Epilepsy.—According to Buchthal electroencephalography makes it possible not only to analyze the mechanism of the epileptic attack and the place of origin but also to examine the condition in the free interval. The changed threshold in cortical and/or subcortical parts of the brain is as a rule manifest before and during the attack and will be seen electroencephalographically. With few exceptions attacks without electroencephalographic changes are functional. Many conditions formerly believed to be functional are masked epileptic disturbances, especially localized in the temporal region. A normal electroencephalogram during the free interval does not exclude epilepsy. In diagnosis and determination of treatment the case history and observation of an attack are most important. The electroencephalographic examination often decisively supplements the clinical examination. When the anamnestic information is vague and no attack has been observed, positive findings in the electroencephalogram often determine the diagnosis. Abnormal frequency in the electroencephalogram appears in the form, amplitude, and frequency of the waves. Registration during the attack will by and large reveal three patterns: an extreme acceleration in the frequency and amplitude of the deflections, extremely low frequency of large amplitude (the more uncharacteristic psychomotor or temporal attacks), and a regular alternation between potentials of short and long duration (petit mal).

Tumors of the Mediastinum. J. Prévost and L. Décarie.—p. 725.
Considerations on Some Inoperable Cases of Cancer of the Esophagus Treated by Roentgenotherapy During the Years of 1951 to 1952. P. Brodeur and S. Lauzé.—p. 750.
*Bronchopulmonary Cancer: Statistical Analysis of 125 Cases. E. D. Gagnon.—p. 767.
Clinical Considerations on Asthma and Its Treatment. J. Léger.—p. 775.

Bronchopulmonary Cancer.—Since February, 1949, bronchopulmonary cancer was observed in 120 men and 5 women admitted to the thoracic clinic of the Notre-Dame Hospital in Montreal. Of the 125 patients, 97 were over 50 years; the oldest was 79 and the youngest 21. Fifty patients smoked more than 20 cigarettes daily, 38 patients smoked less than 20 cigarettes daily, and 10 did not smoke. The author is doubtful as to the significance of tobacco particularly in the form of cigarettes as an etiologic cause of bronchopulmonary cancer. Cough associated with asthenia, dyspnea, pain in the thorax, or loss of weight was the most frequent symptom. Most of the patients first seemed to have "grippe." One should strongly suspect bronchopulmonary cancer in a man over 40 who continues to cough after the other symptoms of the "grippe" have subsided. It is also important to remember that recurrent pneumonia due to pulmonary atelectasis in a man of this age may be indicative of bronchopulmonary cancer. Hemoptysis should be considered as a danger sign, which induces the patient to seek medical advice, rather than an initial symptom of bronchogenic cancer. All persistent respiratory changes that do not subside in a man past 40 after treatment for four weeks should raise suspicion of bronchopulmonary cancer. Of the diagnostic means, roentgenographic examination and bronchoscopy are the most important. Of the 82 patients in whom bronchoscopy was performed, 52 showed gross changes in the bronchial tree suggesting a neoplasm, and in 38 a biopsy established the diagnosis. Of 81 patients whose sputum was examined cytologically, the diagnosis of bronchopulmonary carcinoma was established in 10 (12.3%); results of the cytological examination were doubtful in 16 patients and negative in 55 patients. Exploratory thoracotomy established the diagnosis of bronchopulmonary carcinoma in 29 patients; but in only 19 of these could pneumonectomy be carried out. Exploratory thoracotomy is the last means of diagnosis in patients with clinical, roentgenologic, or bronchoscopic evidence of cancer of the lung. Routine roentgenography should be considered the vanguard in the detection of bronchopulmonary cancer. Of the 19 patients submitted to pneumonectomy, 3 died during the postoperative period. Of the remaining 16, 9 died within one year. Of the seven survivors 3 were followed up for two to four years and did not show any symptoms of recurrence or of metastasis. In the remaining four the follow-up was too short for drawing any conclusions. Early detection of the disease by routine roentgenography and thorough examination of men over 40 with respiratory changes may improve the statistics of survival.

BOOK REVIEWS

Nutrition and Diet in Health and Disease. By James S. McLester, M.D., and William J. Darby, M.D., Ph.D., Professor of Biochemistry and Director of Division of Nutrition, Vanderbilt University, Nashville. Sixth edition. Cloth. $10. Pp. 710, with 14 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1952.

This has always been one of the standard reference books in this field, and, with William J. Darby as collaborating author for the first time, the present edition is no less complete and authoritative than previous editions. It has been brought up-to-date by the addition of new material that accumulates so rapidly that assimilation and selection become a bewildering task. The final 84 pages of this volume are devoted to an appendix containing valuable tables of food composition, arranged in a variety of ways to be of greatest value in the planning of diets. Part 1 of the text is concerned with physiological concepts and biochemical information underlying the science of nutrition, with separate chapters on proteins, minerals, vitamins, energy metabolism, infant feeding, and normal diets. This section constitutes a complete and concise review of these subjects that will be acceptable to special students of clinical and experimental nutrition and of enormous value to practicing physicians and to persons interested in collateral fields of biological and social science.

Brevity of treatment is obviously necessary in a text of this sort that does not pretend to be a complete encyclopedia of the science of nutrition. Supplementary reading is invited by a comprehensive bibliography at the end of each chapter. Part 2 consists of separate discussions of the nutritional problems involved in individual disease entities. There are sections on vitamin deficiency diseases, diabetes mellitus, gout, obesity and leanness, allergies, and renal, digestive, febrile, cardiovascular, hematological, endocrine, and dermatological diseases. Especially commendable is the sane and well-informed point of view expressed concerning numerous controversial subjects. Of these, two in particular may be cited. The importance of quantitative dietary purines in gout has recently been the subject of much study and disagreement. Despite convincing evidence that the purine nucleus can be synthesized from simpler compounds, there is still reason to believe that a low purine intake is beneficial in the treatment of gout. Similarly, the dispute relative to low cholesterol intake in prevention of atherosclerosis cannot be settled at this time. The text in this volume points out that animal experiments demonstrating the induction of this condition through feeding of high cholesterol diets establishes conditions that have no direct counterpart in man. Emphasis is correctly placed on the need for a conservative attitude toward these trends, with much greater importance attached to the control of obesity as the major preventive of degenerative vascular diseases.

One section, under the guest authorship of Dr. Charles Lund of Boston, is devoted to the difficult problems encountered in relation to both the preoperative and postoperative care of surgical patients. Inclusion of such a discussion is adequate testimony to the growing importance of nutrition in the total concept of surgical therapy. The last chapter provides an interesting discussion of nutrition in industry that is a pertinent and timely recognition of an often unappreciated social and medical problem.

The volume is clearly written, comprehensive in scope, and nicely balanced in treatment of subject matter. It is abundantly illustrated with charts, graphs, and tables but contains no photographs. It combines, in optimal proportion, the physiological and biochemical background for the science of nutrition with an abundance of practical information that greatly augments its utility over other volumes that are overbalanced in either one direction or the other. It should be in the library of every serious student of nutrition, particularly of those in the clinical fields.

Mention may be made of the omission of any unified consideration of nutrition in relation to dental health. The subject is mentioned only briefly in the discussion of the biological function of fluorine. A section dealing with this field would widen the scope of usefulness of the book and provide recognition of the growing conviction that nutrition and diet are of fundamental importance in the maintenance of dental health and the prevention of dental disease.

For Girls Only: The Doctor Discusses the Mysteries of Womanhood. By Frank Howard Richardson, M.D. Cloth. $2.50. Pp. 98. Tupper and Love, Inc., 1090 Capitol Ave., S.E., Atlanta 2, Georgia, 1953.

Sensible discussion characterizes this small volume, even though at times there is a tendency for the writing to become somewhat ponderous. In all but 2 of the 14 chapters, the scene is a girls' summer camp, an especially appropriate setting for the frank discussions that are presented. Most of the constructive suggestions are made by the camp directress, who speaks informally to the girls at special gatherings, but another character, in the person of a woman physician, handles the semitechnical aspects of body changes during adolescence, sexual maturation, and pregnancy. Especially well done are the chapters on petting, the difficulties girls have in understanding their mothers, and the problems mothers have in getting along with their adolescent daughters. All parents can probably benefit from this volume as much as can their daughters, and the reading of it might well be recommended as a cooperative family project.

Adventures in Artificial Respiration. By Peter V. Karpovich, M.D., Professor of Physiology, Springfield College, Springfield, Massachusetts Cloth. $7.50. Pp. 303, with 126 illustrations. Association Press, National Council of the Y. M. C. A., 291 Broadway, New York 7. 1953.

It seems incredible that 117 different methods of artificial respiration have been developed, but the author of this volume gives descriptions, facts, and dates for that many. The methods described are for infants, and for persons asphyxiated by drowning, stove gas, war gases, or electrical shock. Special emphasis is given to the Nielsen method of artificial respiration known in the United States as the back pressure-arm lift method. A chapter is devoted to the mechanics of respiration, including principles and common misconceptions. The volume is well documented, and there are many illustrations, pictures, and tables. Members of the medical profession will want the book for the historical development. Members of lifesaving crews and instructors of water safety should have the book as a ready reference.

The Suprarenal Cortex. Edited by J. M. Yoffey. Proceedings of fifth symposium of Colston Research Society held in University of Bristol, April 1st-4th, 1952. Colston papers vol. 5. Cloth. $6.80. Pp. 232, with illustrations. Academic Press Inc., 125 East 23rd St., New York 10; Butterworths Scientific Publications, 4-6 Bell Yard, Temple Bar, London, W.C.2, 1953.

In April, 1952, the Colston Research Society held a symposium at the University of Bristol on the suprarenal cortex. This volume of the proceedings consists of 20 lectures, by many leading research workers, which give an admirable survey of knowledge of the suprarenal at that time; this field is developing so rapidly, however, that some of the concepts presented are already antiquated. Discussions follow the lectures, elucidating many of the topics presented. The topics include the nature of pituitary adrenocorticotropin and its preparation, the microscopic anatomy of the adrenal cortex, the chemistry and physiology of the adrenal steroids, and some clinical applications. Outstanding are papers by C. H. Li on adrenocorticotropin, S. Zuckerman on the adrenogenital relationship, G. F. Morrison on urinary adrenocortical steroids, and D. J. Ingle on physiology of these compounds.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

American Academy of Orthopaedic Surgeons Instructional Course Lectures. Volume X. Editor: Charles N. Pease, M.D. Cloth. $12. Pp. 439, with illustrations. J. W. Edwards, 1745 S. State St., Ann Arbor, Mich., 1953.

As the instructional courses of the American Academy of Orthopaedic Surgeons have increased in their scope and the amount of time given to them, the volume containing these lectures has, of necessity, also increased. The editor should be highly commended on this book, particularly regarding the rapidity with which the volume has made its appearance since these courses were given at the academy meeting less than six months ago. The format of the book is similar to the previous volumes and the excellent size of type makes for easy reading. The many reproductions in the book are excellently done, and so, from a reader's viewpoint, the book is easily read. The present volume is divided into several chapters, which make a nice summary within each chapter. The chapter on braces is of particular interest inasmuch as there are relatively few places where one can learn about proper braces. The chapter on amputations and prostheses of the upper extremity is also rather new and makes extremely interesting reading. This is an excellent reference book and, along with the previous ones of this series, makes a valuable addition to the orthopedic surgeon's library.

Surgery of the Pancreas. By Richard B. Cattell, M.D., Surgeon, Lahey Clinic, New England Baptist Hospital, Boston, and Kenneth W. Warren, M.D., Surgeon, Lahey Clinic. Cloth. $10. Pp. 374, with 100 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

This volume, devoted to pancreatic surgery, is based on a large clinical experience and is therefore an authoritative contribution. The first chapter, devoted to anatomy and physiology, is justifiably concise because the subject is well known. The second chapter, on congenital malformations, is complete. The third chapter, on acute pancreatitis, stresses the modern viewpoint, emphasizing diagnosis and medical management; surgical intervention is considered only under special circumstances. The chapter on chronic relapsing pancreatitis is one of the best in the book and is an outstanding addition to the literature, although general agreement with all principles stated will probably not obtain, as, for example, the excision of the body of the pancreas is to be carried out only when the process is limited to this portion of the gland. The next chapter, dealing with pancreatic cysts, summarizes much of what is known on the subject, but there are certain minor omissions such as mere mention of dermoid cysts and no mention of echinococcus cysts. More consideration of cystadenomas might be expected in a treatise of this sort. The chapter on pancreatic injuries is most complete. The last three chapters are concerned with pancreatic tumors but scant attention is given to carcinoma of the body and tail of the pancreas as a clinicopathological entity. In regard to side-tracking operations for palliation, the authors stress the importance of bile-tract-jejunal anastomosis and, in addition, the anastomosis by T-tube of the obstructed duct of Wirsung to the jejunum. It would have been interesting to note what the authors could say in regard to the subsequent course of the 28 patients with pancreatic duct anastomosis in addition to bile tract enterostomy as compared with those patients who received only the latter procedure, but such a discussion is not given. In the description of pancreatoduodenectomy the writers describe their methods of reimplantation of the pancreatic stump into bowel and only mention briefly that this step is not universally agreed upon and that others often simply ligate the stump with permanent occlusion of external pancreatic secretion.

Among 102 pancreatoduodenectomies (including 2 total pancreatectomies) there were 13 postoperative deaths, i. e., 12.7%. Of 38 survivors from pancreatoduodenectomy for carcinoma of the head of the pancreas, 10 lived less than 7 months, 12 lived 6 months to 1 year, 8 survived 1 to 2 years; 2 lived to 2 to 3 years, 1 lived 5 years. Among the 5 patients still alive, 4 have been living less than 6 months, and one has been living 6 years. Among 28 survivors for carcinoma of the ampulla, 15 are still living, 3 of them for five or more years after operation. Among 5 survivors from carcinoma of the distal common duct, three died 3, 21, and 41 months after operation respectively and two are alive at 7 and 16 months after the operation. Among 5 survivors for carcinoma of the duodenum, four lived 8, 8, 13, and 24 months respectively, and one lived for 18 months after the operation.

The writers are to be congratulated on their use of the term pancreatoduodenectomy rather than pancreacticoduodenectomy. On the other hand, certain features long ago introduced into the literature, and quite probably incorrect, are again perpetuated; for example, in the chapter on total pancreatectomy the cases of Billroth (1884) and of Franke (1900) are again cited although mention is made, quite correctly, that survivals for the period alleged to have occurred could not be possible without insulin and thus a true total pancreatectomy was not performed. Furthermore, the oft-cited case of Rockey as a total pancreatectomy is repeated, when at the necropsy of this patient 1 cc. of pancreatic tissue was discovered. The latter finding is of importance in view of the experiments reported by Dragstedt and others that in dogs retention of a small fragment of pancreas necessitates a higher insulin requirement than when the pancreas is totally removed. Thus Rockey's case should no longer be referred to as a true total pancreatectomy.

The value of this book is greatly enhanced by the profusion of excellent diagrams of surgical procedures, and beautiful reproductions of roentgenograms well chosen to illustrate various facts. Another outstanding feature is the extensive bibliography at the end of each chapter. The print is large and easily read, and the paper and binding are of the highest quality. This contribution is certainly the most up-to-date work in this field at present, and for this reason is of great value to all those doing abdominal surgery.

The Gold-Headed Cane. [By William Macmichael, M.D., 1827.] With foreword by James J. Waring, M.D., and preface by William J. Kerr, M.D. Containing text and illustrations of fifth edition [1923], including introduction by George C. Peachey and his annotations. Seventh edition Cloth. $6.50. Pp. 186, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1953.

For some years Dr. Kerr has been convinced of the need to arouse in medical students a greater interest in the welfare of patients. The "gold-headed cane" has provided him with an inspiring device "for bringing the Art of Medicine more forcibly to the attention of students, faculty and of all those concerned with the care of patients." This award is granted annually in a fitting ceremony at the University of California School of Medicine; the gold-headed cane serves to augment and embellish other rewards of recognition for scholarship by emphasizing the fact that its recipient possesses qualities inherent in the well-educated physician. The history of the gold-headed cane extends over a period of more than 130 years. The fashionable doctor of the 18th century was somewhat of a dandy, with velvet or satin coat, a wig and three-cornered hat, buckskin breeches, top boots or stockings, buckled shoes, gloves, and even a muff. An essential part of the physician's equipment at the time was a cane, with a gold or silver top, made perforated and hollow so that it could contain an aromatic compound believed capable of preventing infection.

This book deals with the earliest traditions of the gold-headed cane. In its pages will be met John Radcliffe (1650-1729), who was physician to King William and Queen Mary of England and who first made the remark, since attributed to others, that "as a young practitioner he possessed twenty remedies for every disease, and at the close of his career he found twenty diseases for which he had not one remedy." Radcliffe carried a gold-headed cane and passed it on to his successor in medical practice, Richard Mean. In turn the cane was passed along to various successive physicians who carried it to meetings of the medically learned; early in the 19th century it was deposited in the Royal College of Physicians, where it remains to this day. An account of some of the physicians who carried the cane was first published in 1827 by William Macmichael, a second edition appearing in 1828, and a third in 1884. The reissue (1923) by George Peachey was chosen for the present seventh edition.

Man's Foods: Nutrition and Environments in Food Gathering Times and Food Producing Times. By Lloyd B. Jensen, Ph.D. Cloth. $4.50. Pp. 278. Garrard Press, 119-123 W. Park Ave., Champaign, Ill., 1953.

This book deals with a survey of man's food from paleolithic epochs to the close of classical times, and includes a discussion of the nutritional influences of various foods on man's development. The author, whose professional fields are microbiology and food technology, has been interested in ethnic history and prehistoric culture since his youth. Even with this backgound, preparation of this volume must have been a formidable task. The book contains a wealth of interesting material from many heterogenous fields, but, unfortunately, the facts and theories presented are not well organized into a smooth, sequential whole. The reader is disconcerted by being transported back and forth between prehistoric and modern times on innumerable occasions. The style of writing does not permit easy reading. Less detailed documentation and more generalization would have added to the appeal of this book for both laymen and professional persons. The first two sections of the book, which deal with food gathering times and food producing times, provide many valuable references and interesting conjectures. The third section, entitled "Foods, Environment, and Man's Nutrition," includes miscellaneous notes on relationships of nutrition to climatic stress, bodily changes and man's welfare, the social aspects of nutrition, and early preparation of food. This book should be of greater interest to the anthropologist, sociologist, and historian than to the biochemist or physician.

A Translation of Luigi Galvani's De viribus electricitatis in motu musculari commentarius. Commentary on the Effect of Electricity on Muscular Motion. By Robert Montraville Green, M.D. Cloth. $4. Pp. 97, with 4 illustrations. Elizabeth Licht, Publisher, 30 Hillside Ave., Cambridge 40, Mass., 1953.

Galvani's account of his pioneer experiments in electrophysiology was published in Latin in 1791 and subsequently translated into Italian, German, and French. According to the preface, however, this is the first appearance of the work in English. It is desirable that Galvani's own account be made more widely available to students in this way, for the modest and straightforward manner in which he set forth these epoch-making facts makes one deplore the pressures that necessitate the publicity-conscious maneuvering with which scientific discoveries, real and fancied, are announced today. Another timely feature of the book is Pupilli's biographical introduction, for it records Galvani's conflict with the politicians of the Cisalpine Republic that had been created by Napoleon and the consequent poverty of the last days of Galvani's life.

The difficulties of rendering the complex sentences of the original Latin into readable English have been met expertly by the translator; the supplementary material has been well chosen; there are some interesting illustrations; and the publisher has contributed an attractive format. This book is recommended to students of physiology and medical history.

The Neurophysiological Basis of Mind: The Principles of Neurophysiology. By John Carew Eccles, Professor of Physiology, Australian National University, Canberra. Waynflete lectures delivered in College of St. Mary Magdalen, Oxford, in Hilary Term, 1952. Cloth. Pp. 314, with 89 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E.C.4, 1953.

This monograph on neurophysiology is built on a series of lectures delivered at Oxford in 1952. The subject of synaptic transmission is the main theme of the lectures, and, as the author states, the contributions of his own laboratory have been given disproportionate emphasis. The first two chapters are concerned with the theories regarding the transmission of the impulse along the course of the nerve. The ionic hypothesis of the resting and active membrane is discussed in detail. The author invokes the hypothesis of a "sodium pump" to explain the interchange of ions across the membrane and does not consider the possibility that acetylcholine may play some role in the diffusion of the ions by altering the permeability of the membrane. The third and fourth chapters deal with the transmission of the impulse at the peripheral junction and in the central nervous system. In these chapters the conclusions are in agreement with the generally accepted viewpoint. The last four chapters deal with central inhibition, prolonged functional changes (plasticity) in the nervous system, transmission within the cerebral cortex, and the mind-brain problem. The statements in these chapters are conjectural and highly speculative, without basis of sound experimental evidence.

The book is well printed and illustrated by a large number of diagrams and models to clarify the text. The subject matter is highly technical, and the book will be of interest only to physiologists, particularly those who have a special knowledge of electrophysiology. It might be added that the title of the book is misleading in that the subject matter is primarily the transmission of impulses. The author has failed to elucidate the neurophysiological basis of mind.

Sehnenverletzungen und Sehnen-Muskeltransplantationen. Von A. N. Witt, Privatdozent Oberarzt des Versorgungskrankenhauses Bad Tölz. Cloth. 32.80 marks. Pp. 164, with 122 illustrations. J. F. Bergmann, Trogerstrasse 56, München 27, 1953.

This book affords a ready source of reliable information on tendon injuries and transplantations. The literature on this subject that has accumulated in the past 15 years is voluminous. The author has covered this material well, particularly that originating in America, Italy, England, France, and Germany. The subject matter is directed to both the specialist and the general surgeon. The stress placed on the physiopathology of tendon mechanisms is especially commendable. Substitution procedures are admirably presented. This monograph is not solely theoretical but represents the author's personal experience gained while doing work at the State Hospital (Staatl Versorgungskrankenhaus), Bad Tölz. The simple pen-and-ink sketches and the many fine photographs demonstrate pathology and procedures adequately. An extensive bibliography is appended at the end of the text. This book is recommended to anyone who is interested in this subject and who has a comprehensive reading knowledge of German.

The Metabolism of the Tubercle Bacillus. By William F. Drea, D.M.D., Associate Laboratory Director, Colorado Foundation for Research in Tuberculosis, Colorado College, Colorado Springs, and Anatole Andrejew, I.C., Research Staff, National Center for Scientific Research in France, Pasteur Institute, Paris. With foreword by Esmond R. Long, M.D., Ph.D., Sc.D., Director of Pathology, University of Pennsylvania, Philadelphia. Cloth. $12.50. Pp. 448, with 24 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1953.

This is a timely compilation of the literature and the authors' experiences that adds a needed reference volume to those of Calmette and Wells. Long, in the foreword, notes that a great deal of information accumulated in the last 30 years is coordinated here. Both authors are pioneers in the study of important phases of the problem under consideration, and their personal investigations led to the preparation of this monograph. Drea is a student of subsurface growth and Andrejew, of the mechanisms involved in respiration of the bacillus. The chapters on nutrition and respiration cover the fundamental physiology of tubercle bacilli, with a comprehensive review of the older literature. The chapter on depth growth is the most important in the monograph. It is based on the work of Drea and Boissevain, 10 years ago, that resulted in striking rapidity of growth from minute inoculums in simple mediums. Andrejew, through special skills, elucidates the problems of oxygen utilization in subsurface growth. The fourth chapter, on enzyme systems, furnishes information of specific as well as general interest on enzyme systems and indicates the paucity of applicable information with regard to the tubercle bacillus. The closing chapter contains a detailed review of chemical studies of the bacillus and its products. When possible or desirable, comparison with other acid-fast or nonacid-fast micro-organisms is made. The monograph is unique and will not be duplicated until new data on the tubercle bacillus, its metabolism, and its virulence appear. This, however, requires long painstaking study because of the slow growth, persistence and natural biological possibilities of the micro-organism.

QUERIES AND MINOR NOTES

EIGHTH NERVE DAMAGE FROM STREPTOMYCIN

To the Editor:—*What therapy is indicated for involvement of the eighth cranial nerve in prolonged streptomycin therapy?* M.D., *Pennsylvania.*

Answer.—There is no specific antidote for damage to the eighth nerve from streptomycin. There is usually some spontaneous recovery of function in the first six months after therapy with the drug has been stopped. Adequate doses of complete B complex vitamins are theoretically beneficial to the injured nerve, but there has been no proof of their effectiveness. When the damage is confined to the vestibular nerve, adequate compensation is established by the body in the course of a year or two in younger persons; in older persons compensation occurs more slowly and is not so complete. Head and bending exercises, as described by Cawthorne, are helpful in hastening this adaptation of the organism to the loss of the vestibular nerves. When the acoustic division of the eighth nerve has been effected, there is no specific therapy. The best treatment of streptomycin damage to the eighth nerve is prevention, that is, the avoidance of dihydrostreptomycin, which is particularly toxic to the acoustic division, and the limitation of streptomycin to a dose of 1 gm. daily, with prompt withdrawal of the drug at the first evidence of loss of vestibular response.

METASTATIC NEUROBLASTOMA

To the Editor:—*I would appreciate information on treatment for an 11-year-old girl with metastatic neuroblastoma of the lungs and pelvis. The original tumor was removed from the right kidney area, and the patient has had several courses of x-ray therapy, which has partially controlled the growth of the lesions. Her parents are aware of the ultimate prognosis but are constantly plagued by persons who suggest various "cures." Is there anything that may be of benefit?* M.D., *Wisconsin.*

Answer.—Certain patients with neuroblastoma widely metastatic have shown transient incomplete regression of the lesions when treated with compounds having activity as folic acid antagonists. Amethopterin and 4-aminopteroylglutamic acid (Aminopterin) are the compounds usually employed. Radiation therapy has long had a role in temporary control of these lesions. Rare instances of spontaneous improvement have been encountered. No form of dietary therapy has been shown to have salutary effects, nor has the use of any radioactive isotope.

HEARING OF THE PULSE IN THE EAR

To the Editor:—*What is the cause of and treatment for hearing of the pulse in the right ear? There is no pain and no deafness. The pulse is distinctly heard when the patient is in any position but particularly when he becomes quiet or is lying down. There is no continuous murmur. This condition has been gradually developing for months.*

C. F. Upchurch, M.D., Oceana, W. Va.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—The hearing of a murmur in the ears is fairly common. A single rush of blood may be heard with each cardiac cycle, or the sound may be split. These sounds are usually heard when the patient is recumbent and when all other noises are absent. At this time, the hearing apparatus becomes exquisitely sensitive to these bruits, which otherwise are lost in the general noise level. The bruits are particularly noticeable when air absorbed in the middle ear is not replaced. They may be amplified by closing of the external auditory canal by, for example, a pillow. Sometimes the sound can be eliminated by swallowing or by blowing air into the eustachian tube. The internal carotid artery passes close by the internal ear, and its vibration may be transmitted to the cochlea. Hypersensitive persons may focus special attention on these noises. In these, reassurance is usually sufficient to eliminate the special attention given to the noises. These bruits become commoner in and after middle age. The presence of a unilateral progressive bruit calls for special investigation. Occasionally, it may indicate the presence of an intracranial arteriovenous aneurysm. Such bruits may be sufficiently loud to be heard by direct auscultation. Arteriovenous aneurysms with unilateral bruit may develop after severe skull injury. Neurological examination may establish the site of the lesion. X-ray investigation may rarely show such aneurysms.

Answer.—The internal carotid artery in its canal through the petrous bone passes close by the inner ear. A patient may occasionally hear his pulse under physiological conditions, such as tight closing of the external canal by impacted cerumen or by resting of the head on and occluding of the ear by an arm or a pillow, in absolute quiet; the artificially increased bone conduction makes possible the perception of the sound of the pulsation. The pulse may be heard also during increased activity of the heart (as the result of physical exercise or emotional excitement). Some clinicians contend that all of these conditions act directly or indirectly on the blood supply to the auditory neural elements or their supporting tissues. Aneurysm of the internal carotid artery and other cardiovascular disorders may cause excessive sound, which could be transmitted to the inner ear. Similarly, angiogenetic neoplasms in the vicinity of the petrous bone could cause such a symptom. In some instances this type of pulsation may even be heard directly or through an otoscopic diagnostic tube by the examiner (objective tinnitus). Hypertensive states may also play a role. A pulsating sound or subjective ear noise may be present as a psychosomatic manifestation. The normal sound of circulation, which is below the threshold of perception, may become noticeable. Proper treatment may be determined only by extensive clinical study to find the cause of the symptom. Apart from a comprehensive investigation of the auditory mechanism, all constitutional influences must be duly considered. It should be borne in mind that pulsating tinnitus may occur independently of ear disease or it may be aggravated by some underlying general condition.

PENILE INDURATION

To the Editor:—*A married clergyman, aged 50, who has three children, for three months has complained that during intercourse his penis angulates at about a 45 to 60 degree angle to the right. There is no pain. He has never had any other genitourinary disorder, and physical examination reveals no abnormality. The prostate and scrotal contents appear normal. What is the cause and the treatment?* M.D., *New York.*

Answer.—From the data offered in this case, it would seem that the clergyman's symptoms are caused by Peyronie's disease. This condition, also called fibrous cavernitis or penile induration, results from induration of the corpora cavernosa in the penis. In most cases, the lesion is self-limiting and the symptoms become ameliorated in the course of time. Good results have been reported recently in treating this condition with cortisone. Radium packs have been used with good results in a small percentage of these cases. Surgical treatment has also been tried in some cases, but as a rule the results have not been satisfactory.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

LOUD FETAL HEART MURMUR

To the Editor:—*An obstetric patient had no complications, but about one month prior to term I heard a loud, blowing, systolic fetal heart murmur, which persisted at every examination. I have never heard such a sound before. It was not a uterine souffle or any other sound of pregnancy. It definitely was synchronous with the fetal heart beat. Am I right in assuming that it was due to patent ductus arteriosis?* *William B. Gerlach, M.D., Harlowton, Mont.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—It is not likely that the murmur was due to patent ductus arteriosis. It was probably a fumic or umbilical souffle, which is characterized by a sharp whistling sound, synchronous with the fetal pulse. It can be heard in about 15% of patients and is due to a rush of blood through the umbilical arteries when they are subjected to pressure by torsion, twisting, or tension of the umbilical cord.

Answer.—It is questionable that the systolic murmur heard was due to patent ductus arteriosus. Every newborn child normally has patent ductus arteriosus, which closes shortly after birth. It is extremely difficult to diagnose murmurs in infants during the first six months of life. It is doubly hard to diagnose a murmur in the fetal heart. About all that can be done is to note, from the standpoint of academic interest, that the fetus has a systolic murmur. If the murmur persists after birth, the child will require constant observation before the cause of the murmur can be determined.

CHARCOT'S JOINTS

To the Editor:—*A man, aged 40, has had a Charcot's right knee (neurogenic arthropathy) and a Charcot's left ankle, on a tabetic basis, for 10 years. The joints are badly disintegrated, but, with the support of braces, the patient has been able to pursue his occupation, the operation of heavy equipment. He has had several courses of penicillin therapy and, except for the joint disease, has had no signs of tabes for a long time. He insists on being given yearly courses of 6 million units of penicillin. Recently, the ankle underwent further disintegration, but this seemed to stop during a course of penicillin therapy. I am told that penicillin does not alter the course in Charcot's joint. 1. What are the chances that arthrodesis would be successful? 2. Will a Charcot's joint in which the disease apparently has been arrested for years disintegrate further? 3. Would you advise yearly or half-yearly administration of penicillin to avoid further disintegration of the involved joints?* *M.D., Pennsylvania.*

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—1. Whether arthrodesis of the knee and ankle would be successful can be determined only by an orthopedist on the basis of a personal examination of the patient and roentgenograms. 2. A Charcot's joint can disintegrate further long after the disintegration process seems to have stopped. 3. The apparent effect of penicillin on the ankle disease is the result of chance. No form of antisyphilitic treatment has a beneficial effect on Charcot's arthropathy, the management of which, at least in the knee and ankle, is purely an orthopedic problem. Further antisyphilitic treatment, whether with penicillin or by any other means, is not worth while prophylactically to avoid further destruction of the involved joints or involvement of other joints. The Charcot change is unpredictable, may occur at any time in a patient with long-standing, apparently arrested tabes dorsalis, and is neither preventable nor curable.

Answer.—1. The chances of obtaining a successful arthrodesis of both the knee and ankle on the affected side in patients with neurogenic arthropathy are almost nil. The chances of one of these joints being fused is somewhat better and would be worth a trial; however, adequate braces would probably be just as effective. 2. Charcot's joints in which the disease process appears to have been arrested for several years may disintegrate further and often do. There is never any spontaneous improvement from a roentgenologic or functional standpoint. 3. If the tabetic process is arrested, as determined by serologic tests, repeated administration of penicillin will have no objective effect on the arthropathy. It is probable that any effect seen is coincidental or psychic. Furthermore, it will not prevent the development of neurotrophic changes in other joints that are not affected at this time.

DACRYOCYSTITIS

To the Editor:—*What is the most effective treatment for resistant, purulent dacryocystitis?* *W. O. Bailey, M.D., Leesburg, Va.*

Answer.—Dacryocystitis ordinarily is due to an occlusion of the distal end of the lacrimal sac within the nose. The treatment consists essentially of the establishing of a connection between the sac and the nose. This may be done by probing, which usually is not very successful. Recently, a procedure in which a small plastic tube is threaded through the lacrimal punctum into the nose has given satisfactory results. In the event that this proves unsuccessful, the procedure of choice is dacryocystorhinostomy, in which the medial wall of the lacrimal sac is sutured to the nasal mucosa through an opening in the bony wall of the nose. All patients with dacryocystitis should be examined by a rhinologist to exclude the presence of nasal conditions causing obstruction of the nasal lacrimal ostium.

TIRED AND NERVOUS PATIENTS

To the Editor:—*Many patients, especially women, are nervous and tired, have cold intolerance, dry skin and hair, and borderline-low or low basal metabolic rates and borderline-high serum cholesterol. They feel much better while taking from 0.5 to 3 grains (0.03 to 0.3 gm.) of desiccated thyroid; yet, they are said to react normally to radioactive iodine and protein-bound iodine tests. Are these patients at all hypothyroid? If not, does it harm them to take thyroid extract over a long period of time?* *G. V. Lemmon Jr., M.D., Springfield, Mo.*

Answer.—Many patients have basal metabolic rates considerably lower than the average normal level without clinical evidence of thyroid disease and with evidence of normal thyroid function as determined by radioiodine collection by the thyroid gland and by protein-bound iodine of the blood. In many instances this condition has been determined to be a constitutional characteristic. It is frequently accompanied by symptoms of a chronic fatigue state. Some, but by no means all, of these patients may feel better and have less fatigue if they are given a dose of desiccated thyroid that will maintain the basal metabolic rate at or near the average normal level. Occasional clinical observation should be made to be sure that symptoms or signs of hyperthyroidism do not supervene. No demonstrable harm has been reported to result from administration of desiccated thyroid providing the basal metabolic rate has not been raised above normal levels; however, the advantages of this procedure are questionable in most instances. If the basal metabolic rate is elevated by desiccated thyroid over a considerable period of time, cessation of medication may, as Farquharson has pointed out, be followed by a temporary period of hypothyroidism until the thyroid gland has recovered its normal function.

ALOPECIA AREATA

To the Editor:—*What local skin lesion would cause loss of hair on the lateral side of the chin, leaving residual, smooth, baby-like skin the size of a dollar, with no symptoms resembling alopecia areata?* *M.D., New York.*

Answer.—Alopecia areata may occur on areas other than the scalp. The eyebrows and beard area are often affected. In the case described, the presence of a sharply defined patch of smooth skin, devoid of hairs and without signs of inflammation or scars, suggests alopecia areata.

VECTORCARDIOGRAPHY

To the Editor:—*Please send me information on vectorcardiography. What is the principle involved, and what are the practical applications?*

A. R. Powell, M.D., Elkader, Iowa.

Answer.—During the complex spread of the cardiac impulse through the myocardium, areas are created that have been reached by the wave of activation while other, progressively smaller, areas remain to be activated. Similarly a reversal of events takes place during recovery from activation. The net effect of either process results in differences of electric potential in a large number of areas. Those activated can be said to represent the negative pole or source of an electric battery, and those still to be activated, or already deactivated, its positive pole or sink. The electromotive force thus created at any instant of depolarization and repolarization of the heart can be diagrammatically represented by an arrow having a certain direction, a certain length (magnitude of the electromotive force), and a certain orientation (sense) with respect to its positive and negative ends. Such a geometric representation of a force in space is called a vector.

In the heart, the vector is assumed to originate in a central point. It changes its length and direction from moment to moment during ventricular activation and deactivation (and also during that of the auricles), depending on the relative amount of activated and resting cardiac tissue. By connecting the tips of all momentary vectors, two loop-like figures or "vector loops" are obtained, depicting, respectively, the course of activation and deactivation of the ventricular myocardium. Since these vector loops have a certain spatial orientation, their contour will be different if viewed in different planes of the body.

The conventional electrocardiogram is considered to represent the projection of the vector loop on the frontal and transverse plane of the body. Thus, the frontal vector loop can be constructed from leads obtained in this plane (leads 1, 2, 3 and the aV limb leads) by plotting on a coordinate system the size of a deflection, at consecutive time intervals, as measured in two of these leads; and vice versa the contour of the electrocardiogram can be determined by construction, if the contour, direction, and magnitude of the vector loop is known. Methods have been developed for direct recording of vector loops in the different planes, as well as for quick approximate determination of the vectorcardiogram from the conventional electrocardiogram. At present, however, the former method of direct vectorcardiography is too complex, time-consuming, and expensive and the latter method is not accurate enough to replace routine electrocardiography in practice.

CRAMPS ASSOCIATED WITH PREGNANCY

To the Editor:—*I read that 5 grains (0.3 gm.) of quinine gave complete relief of cramps that are associated with pregnancy and that occur at night. I have used this in several cases and have had good results. However, I wonder whether there could be any deleterious effect to the eighth nerve of the fetus or the mother. Kindly give an opinion about the use of quinine for this condition.*

R. J. Stein, M.D., Pierz, Minn.

Answer.—Since there is some danger in the use of quinine during pregnancy, it would seem that a simpler way to relieve the cramps would be the use of 30 drops of concentrated percomorph liver oil daily. Relief is obtained in one to three days, and the dose can be raised or lowered or discontinued, depending on the relief of symptom. Many things will relieve these cramps, including quinine, cod liver oil, calcium, parathyroid, and activity. They are theoretically caused by local stagnation of blood in the muscle tissue due to low blood pressure and slow pulse rate that is often present and normal during pregnancy. According to this theory, lactic acid accumulates and causes the cramps because of its toxicity. The leg cramps are also present in many nonpregnant women as well as men and often are relieved by the same treatment.

POLYCYSTIC RENAL DISEASE

To the Editor:—*A young woman in good health has given birth to two full-term babies. Both pregnancies and deliveries were uneventful, but neither baby lived more than a few hours. In each instance the cause of death, as determined by autopsy, was found to be polycystic kidney disease. Both the wife and husband have been studied by excretory urography, and there is no evidence of renal anomaly. There is also no family history of kidney disease. This couple wants to know what the probability is that a third child may have polycystic kidney disease.*

M.D., Washington, D. C.

Answer.—The influence of heredity in the incidence of polycystic renal disease is of major importance. The mere fact that a denial of renal disease is made by the parents of polycystic babies is insufficient. A meticulous study for evidence of renal disease in all members of both families should be made in parents and grandparents, uncles and aunts, and brothers and sisters. It is well known that such inheritance may skip a generation and may be present in only one or two of several children. The clinical evidence of polycystic kidney in adults may be obscure. In some cases the presence of hypertension alone will be the clue. The diagnosis of polycystic kidney cannot be excluded by excretory urography alone. In the early decades the deformity may be limited. Furthermore, excretory urography frequently may not visualize minor deformity, and clear retrograde pyelograms should be made in order to do so. Since the disease may not occur in all children of families, there is a possibility that a third child may be born without this lesion. On the other hand, since both infants had evidence of polycystic disease, it is doubtful whether the couple should be encouraged to have more children.

INSECTICIDE TOXICITY

To the Editor:—*What are the health hazards from using a heavy fog of gamma benzene hexachloride in a fogging machine? Are mosquitoes more easily killed by it than flies? Are there not better and less dangerous ways of getting rid of mosquitoes than by fogging?*

M.D., Pennsylvania.

Answer.—The use of a heavy fog of gamma benzene hexachloride in a fogging machine outdoors has not been found to result in injury to health even though this operation has been conducted extensively over many areas of the country during the last few years. The person who would be most likely to receive excessive exposure would be the operator of the fogging machine. Benzene hexachloride will hold mosquito larvae in check with appreciably lower concentrations than are necessary to prevent the emergence of house-fly larvae. The benzene hexachloride was found to be the most effective of a group of 33 insecticides in killing mosquitoes. The predominating factor in the toxicology of gamma benzene hexachloride is stimulation of the central nervous system resulting in hyperirritability and lack of muscular coordination. Excessive exposure may cause death. Absorption can take place through the gastrointestinal tract, the respiratory tract, and the skin. Storage is greatest in the fatty tissues, but significant amounts are deposited in the liver and kidneys. Absorption through the gastrointestinal tract is of relatively low order, but the customary precautions against prolonged and extensive inhalation should be observed.

COUNTING OF CHROMOSOMES

To the Editor:—*By the use of electron microscopy, has any investigator been able to count the chromosomes in the cells of human tissue?*

Luther M. Strayer Jr., M.D., Bridgeport, Conn.

Answer.—It is not necessary to use the electron microscope to count human chromosomes, because they are large enough to be seen and counted by an ordinary microscope. In fact, to use an electron microscope for this purpose introduces many difficulties.

VAGOTOMY AS A PROPHYLACTIC AND CURATIVE PROCEDURE IN PEPTIC ULCER

Waltman Walters, M.D.
and
Donald P. Chance, M.D., Rochester, Minn.

As long as the cause of peptic ulceration remains unknown, which unfortunately will probably be a long time, the methods used for its correction will vary and so will the results. This variation will depend on the knowledge and experience of the internist and the surgeon, and on the response of the patient to the method used to reduce gastrospasm by decreasing the quantity and concentration of hydrochloric acid secreted by the stomach. Variation also depends on the ability to develop the patient's insight and knowledge of the association of peptic ulcer with nervous and emotional disturbances. Of even greater importance is the response of the individual patient's gastrointestinal mucosa to the digestive action of gastric secretion.

Only about 13% of the patients suffering from duodenal ulcer who have come to the Mayo Clinic in recent years have required surgical treatment. These patients had complications with which we are all familiar. In these cases the internists and surgeons advised operations since medical management was no longer feasible and was likely to be followed by untoward results. The other 87% of patients with duodenal ulcer have been provided with a medical regimen because of a short history of ulcer or no previous trial of good medical treatment and because no complications were present.

The patient with gastric ulcer needs a different program of treatment, for gastric ulceration differs in many ways from duodenal ulceration. When operation is necessary for gastric ulcer and the ulcerating lesion is removed by partial gastrectomy, the results are excellent in practically every case, recurrent ulceration never occurs, and the operative risk is less than 2%. Obviously there is no place for vagotomy alone in the treatment of such lesions, for it leaves behind an ulcerating lesion that has a 20% chance of becoming malignant. When vagotomy has been used, it has been followed by a high recurrence rate for benign gastric ulceration and a high incidence of troublesome digestive symptoms due to the atonic stomach, which does not empty satisfactorily. Happily, few surgeons continue to use vagotomy in the treatment of gastric ulcer.

We will confine our remarks for the most part, therefore, to the use of vagotomy in the treatment of duodenal ulcer and to ulcer recurring after either gastric resection or a gastroenterostomy. We will try to answer the following questions and a few others that will be suggested by the discussion. 1. Will vagotomy alone cause healing of duodenal and gastric ulcers? 2. Will vagotomy added to gastroenterostomy improve the results of gastroenterostomy alone for duodenal ulcer? How do these results compare with those of gastric resection with and without vagotomy? 3. Will vagotomy alone cause healing of gastrojejunal ulcers which may follow (*a*) gastroenterostomy or (*b*) gastric resection, and in what comparative proportions? 4. Which type of treatment, vagotomy, gastric resection, or reresection, yields better functional results and lower recurrence rates in cases of gastrojejunal ulcer after gastroenterostomy or gastric resection?

SURGICAL TREATMENT OF DUODENAL ULCER EXCLUSIVE OF VAGOTOMY

Before the results of vagotomy in the prevention and treatment of peptic ulceration are discussed, it is first necessary to describe the results of treatment of duodenal ulcer by pyloroplasty, gastroenterostomy, and gastric resection without vagotomy. Each of these procedures will cause the ulcer to heal and in most cases will prevent recurrence. This is especially true of properly performed gastric resection.

From the surgical standpoint, operations for chronic duodenal ulcer are directed toward relieving pyloric or duodenal obstruction due to pylorospasm associated with a small ulcer or to an obstructing ulcer. The aim is to reduce gastric acidity preferably to a relative achlorhydria, and, when possible, with pyloroplasty and gastric resection to remove the duodenal ulcer.

Assistant to the Staff, Mayo Clinic (Dr. Chance).

From the Division of Surgery, Mayo Clinic.

Read before the Section on Gastroenterology and Proctology at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

In the early twenties, when 50% of patients with duodenal ulcer who came to the Mayo Clinic were operated on, many with small nonobstructing ulcers, pyloroplasty or gastroduodenostomy with removal of the ulcer frequently gave surprisingly good results with regard to relief of symptoms of ulcer. The operative risk was low, being about 1% or less. Unfortunately, since gastric acidity was not lowered, for the gastric antrum remained, and because some gastric stasis occurred, the ulcers recurred in a high percentage of cases and these operations were abandoned. In recent years, equally good results have been obtained in cases of ulcer of similar type by nonsurgical methods directed to the relief of pylorospasm and reduction of gastric acidity.

Gastroenterostomy has been used extensively and with splendid results in the treatment of chronic duodenal ulcer that caused varying degrees of pyloric obstruction; however, ulceration sometimes recurred. It recurred in from 4 to 6% of the clinic's cases[1] and in 10% of the cases reported by Lorenz.[2] These patients were operated on, for the most part, during and after World War I when the German and Austrian people had been subjected to the strains of a terrible war during which time, and for years afterward, they had received inadequate food, especially proteins, fats, and vitamins, for the maintenance of a normal nutritional state. Recurrent ulceration was proved in 18% of the cases and suspected in another 16% of the cases reported by Berg and Lewishon.[3] Although mention is not made of the nationality of the patients in the reports from Mount Sinai Hospital, it may be assumed that the majority were Jews, among whom recurrent ulceration is greatly increased.

When ulceration did not recur, the patient obtained complete relief of symptoms of ulcer, had few evidences of gastrointestinal dysfunction, and the duodenal ulcer always healed unless obstruction occurred at the gastrojejunal stoma. Then and only then might reactivation of the duodenal ulcer occur. There must be thousands of patients who have undergone gastroenterostomy and who are living normal lives today, and this operation continues to be used at the clinic in selected cases. It is now employed by us in about 10% of cases of duodenal ulcer treated surgically whereas gastric resection is used in about 80%.

Gastric resection took the place of gastroenterostomy in treatment of chronic duodenal ulcer at the clinic because the rate of recurrence was only about 2% after this operation. Furthermore, after operation the patient could eat and drink what he liked, within reason, and the results were, for the most part, excellent. Some untoward symptoms of minor character, however, sometimes occur. These, for example, are loss of, or inability to gain, weight, or symptoms related to rapid emptying of the stomach with distention of the intestine, either the jejunum or duodenum, to which it was anastomosed. This disturbance was called the "dumping syndrome." At first the risk of gastric resection for duodenal ulcer varied from 3.5 to 10%, but, as surgeons became more familiar with the indications for removing the duodenal ulcer, or leaving it, and for closing the duodenal stump so that leakage would not occur, the operative risk in properly selected cases and for properly executed operations dropped to approximately 1.5%.[4] As examples of this, we would like to quote from several recent reports.

In the series of McDonald, Gillespie, and LaBree[5] from the Duluth Clinic, presented at the last meeting of the Central Surgical Association, the mortality rate from gastric resection decreased from 6.3% of 93 patients operated on five to nine years ago to zero for the last 141 consecutive resections performed in the years 1948 through 1952. Follow-up studies in 68 patients five to nine years after operation showed that 94% were able to resume preoperative duties and that in the 1948-1952 series 92% of their patients had excellent results, with loss of weight occurring in 12% and 20% of their two series respectively.

Kline,[6] speaking at the meeting of the Southern Medical Association, Nov. 5 to 8, 1951, reported on 357 resections for benign lesions of the stomach and duodenum with a mortality rate of 0.3%. Kline had performed the operations in 250 cases, and the other operations were done under his direct supervision.

The experience at the Mayo Clinic is similar. Approximately 90% of our patients have excellent results, about 10% have mild digestive symptoms, not of the type caused by ulcer. The hospital mortality rate was 1.5% for the 409 gastric resections for duodenal ulcer performed in 1952. We have averaged about a 2% ulcer recurrence rate.

VAGOTOMY

The truest and best test of what vagotomy will accomplish in the way of healing of a peptic ulcer is to note its effect on duodenal and gastric ulcers in which no other operation is performed, for whatever reason, especially when the associated operations that have been used to prevent gastric stasis of themselves will cause such ulcers to heal. In our experience vagotomy alone in the treatment of duodenal ulcer has given excellent results in only 64% of cases, with evidence of failure to heal, or recurrence, in 16%.

Dragstedt and Woodward[7] reported on 234 patients with duodenal ulcers treated by vagotomy alone. Of these, 76% secured a good result, 9% a fair result, and 15% a poor result. These data were part of a statistical study of 509 patients who had undergone vagotomy and were followed one to seven years.

One of us (W. W.) used the operation in seven cases of gastric ulcer: In one the ulcer failed to heal, and in another it seemed to heal but recurred a year or so later. Gastric resection with removal of the ulcer was followed by an excellent result in both these cases. One patient with a high gastric ulcer and associated gastritis who has been followed for seven years has had an excellent result from vagotomy. Roentgenograms of the stomach have failed to show any evidence of recurring ulcer, although dilatation of his stomach had continued and so had the gastritis to the last gastroscopic examination four years ago. This was three years after the vagotomy. This patient was last examined at the clinic on May 13, 1953. Dragstedt and Woodward [7] reported results of 26 vagotomy operations on patients with gastric ulcers. Sixty-two per cent secured a good result, 15% a fair result, and 23% a poor result.

Whether healing of a gastric or a duodenal ulcer occurs after vagotomy alone is overshadowed by the fact that vagotomy has been combined with gastric resection and gastroenteric anastomosis routinely in recent years for gastric and duodenal ulcer by even the staunchest advocates of vagotomy.

In other words then, vagotomy alone will temporarily heal many duodenal and some gastric ulcers. Perhaps it would heal more if one could be sure that all the vagi were identified and cut, and if there was a more accurate test of the completeness of the vagotomy than we have in the insulin test. Portions of the nerves should be excised for microscopic examination. This has been done routinely on our service. In the cases in which one of us (W. W.) has operated personally, insulin tests have been done 10 to 14 days after operation and were repeated whenever the patient returned. Correlation is good in about 80% of the cases between the result of the test and the clinical results in general, but correlation is poor when recurring ulceration is present. By this we mean that many patients with recurrent ulcers had normal results in insulin tests.* Postoperative insulin tests have given normal results in 74.1% of our patients in which vagotomy with, and without, other gastric operations was performed.

Vagotomy with Gastroenterostomy Compared with Gastric Resection.—In our experience the incidence of recurrence after gastroenterostomy has been 5 to 6%,[1] compared with about 1.1 to 2% after gastric resection. It was our hope that vagotomy when combined with gastroenterostomy would reduce recurrence of ulcer, but unfortunately it has not in our experience. Hoerr,[8] of the Cleveland Clinic, recently reported 147 cases in which gastroenterostomy and vagotomy were performed for duodenal ulcer. Twelve per cent of the operations were considered failures because of persisting or recurring ulcer or symptoms of this. In 1952, one year before, this group reported only 7% failures in their cases. In 15% of the cases diarrhea occurred. Hoerr reported an excellent result (no ulcer pain, no dietary restrictions) in 68% of cases, and good results (no ulcer pain but bloating and vague abdominal distress) in an additional 17%. These latter patients were satisfied with their operation, he said. In 1951, Dragstedt and Woodward [7] reported on 219 patients with duodenal ulcers who were treated by vagotomy plus gastroenterostomy. Eighty-one per cent secured a good result, 10% a fair result, and 9% a poor result.

Adding vagotomy to gastroenterostomy not only has failed to reduce the incidence of recurring ulceration in our experience but has produced troublesome disturbances of motility, such as nausea, fulness, and diarrhea, in 10 to 17% of cases. In some cases another operation, gastric resection, has been required and in others diarrhea has persisted. These results do not compare favorably with those of gastric resection properly performed in properly chosen cases of chronic duodenal ulcer.

The risk of gastroenterostomy with vagotomy and the risk of gastric resection for duodenal ulcer are about similar in our experience. Recently we studied the reports of two series of cases from another institution in which the authors compared results of gastroenterostomy with vagotomy in 175 cases [9] of duodenal ulcer performed at a risk of less than 1% with those of gastric resection in 132 cases, 81 of which were cases of duodenal ulcer. The risk of gastric resection was 3.9%. In the latter group, two of the five deaths following the operation were due to cardiovascular accidents, the remaining were complications that probably would not have occurred had an attempt not been made to remove the ulcer. The "probable or possible" recurrence rate of 5.3% in the second group and the suspected recurrence rate of 9.2% could be attributed to the fact that the pylorus had not been removed but had been excluded in 28 of the 81 cases in which gastric resection was performed for duodenal ulcer. The delayed postoperative complications, and there were many, were due, we believe, to an unwise selection of cases and difficulties with the operation.

Vagotomy with Pyloroplasty.—Vagotomy plus pyloroplasty has largely been abandoned in favor of gastroenterostomy and vagotomy. Crile was an early advocate of pyloroplasty and vagotomy but changed to gastroenterostomy and vagotomy largely, we think, because gastric stasis was greater after pyloroplasty than when gastroenterostomy was performed in its stead. At the beginning of our studies on vagotomy we performed pyloroplasty with vagotomy a few times, but we too abandoned the operation for the reasons mentioned.

Vagotomy, Gastric Resection, and Re-resection in Cases of Gastrojejunal Ulcers Following Gastroenterostomy or Gastric Resection.—In 1947, one of us (W. W.),[10] with associates, after studying and reporting the results of vagotomy with and without associated gastric operations in 66 cases stated that vagotomy is a great contribution to the treatment of recurring ulcer, especially after gastric resection. This statement, which has been reiterated with the passage of years [11] and an increase of the number of cases, continues to be true and we hope will be for many years to come. In a recent follow-up study of patients treated for gastrojejunal ulcer by vagotomy alone at the Mayo Clinic in 1945 through 1952, we found that healing of the ulcer had occurred in 70.5% of 78 traced cases of gastrojejunal ulcer after gastric resection and in 77.8% of 27 traced cases in which the ulcer followed gastroenterostomy (see table).

---

* Abnormal results of insulin tests, as used in this paper, indicate an increase in the quantity of free gastric acidity at the time of greatest hypoglycemia and may be interpreted as evidence of incomplete vagotomy. Normal results of insulin tests as used herein indicate that no increase in the gastric acidity occurred at the time of greatest hypoglycemia and may be interpreted as evidence of complete vagotomy.

Dragstedt and Woodward[7] reported 30 vagotomies performed for gastrojejunal ulcers. Sixteen of these were for gastrojejunal ulcers following partial gastric resection. Eighty-one per cent of the 16 patients secured a good result, 6% a fair result, and 13% a poor result from the procedure. Vagotomy was performed on 14 patients for the treatment of gastrojejunal ulcer following gastroenterostomy. Sixty-five per cent of these patients secured a good result, 14% a fair result, and 21% a poor result. However, gastric resection alone, at the Mayo Clinic, in 1945 through 1952, gave excellent results in 86.5% of 111 traced cases in which gastrojejunal ulcer developed after gastroenterostomy. Results were poor in 9.0% of our traced cases in which gastric resection was employed for gastrojejunal ulcer following gastroenterostomy and in 11.1% of such cases in which treatment consisted of vagotomy alone.

Results of Gastric Resection and Vagotomy for Gastrojejunal Ulcer, 1945-1952

		Mortality		Traced Cases, No.
	No.	No.	%	
Vagotomy	143	3	2.1	125
Gastric resection	158	4	2.5	118

	Traced Cases, No.	Results, %		
		Excellent	Unsatisfactory	Poor
Vagotomy alone				
After previous gastric resection	78	70.5	11.5	18.0
After previous gastroenterostomy	27	77.8	11.1	11.1
Total	105	72.4	11.4	16.2
Vagotomy and gastric resection	11	90.9	9.1	....
Vagotomy and other operations	9	44.5	22.2	33.3
Total for all types of vagotomy	125	72.0	12.0	16.0
Gastric resection				
After previous gastric resection	7	57.1	14.3	28.6
After previous gastroenterostomy	111	86.5	4.5	9.0
Total	118	84.7	5.1	10.2

We have seen extremely large gastrojejunal ulcers develop after adequate gastric resections and heal after vagotomy; the operative risk is approximately 1%. This result is far better and the operative risk is much lower than that of another gastric resection. But vagotomy does not cure all such gastrojejunal ulcers, for in some cases removal of most of the stomach and a second excision of segments of vagus nerves have been required to prevent recurrence of ulcer. In one of the two brief case reports that follow, the vagus nerves had been cut transthoracically and in the other they were reported to have been cut transabdominally at the time of the first gastric resection. The first case illustrates repeated gastric resection and second vagotomy for recurring gastrojejunocolic fistulas.

REPORT OF CASES

Case 1.—The patient was a man 50 years old when he first came to the clinic in 1949. In 1927, symptoms of ulcer had first appeared. In 1934, a perforated duodenal ulcer was closed elsewhere, and in 1935 another perforation made necessary another closure. In May, 1947, gastric resection was performed because of hemorrhage and pain, and in March, 1948, another gastric resection and transabdominal vagotomy were performed for gastrojejunal ulcer.

In January and February, 1949, multiple gastrojejunocolic fistulas and multiple gastrojejunal ulcers developed and the patient consulted the clinic. Results of insulin tests were abnormal. A third resection of the stomach was performed with closure of the colonic fistulas and cautery puncture of the colon. One month later the colonic stoma was closed.

In May, 1949, pain recurred and roentgen therapy to the stomach was without benefit. In August, because of pain and a gastrojejunocolic fistula, all but a small portion of the fundus of the stomach was removed, the colonic fistula was closed, and transabdominal vagotomy was carried out. The patient would not allow postoperative intubation of his stomach, so no gastric acidity studies could be made.

On Feb. 17, 1951, the patient was found to have pulmonary tuberculosis and was admitted to a sanatorium. On March 3, his wife wrote that his stomach condition was good, and on Dec. 10, 1951, a letter reported that he was dismissed from the sanatorium in June and was doing well. The patient returned to the clinic on Dec. 31, 1952, remaining until May 19, 1953, for treatment of pulmonary tuberculosis. He had no indigestion and the gastrointestinal tract was functioning well. When last seen on May 19, 1953, he had no gastrointestinal disturbances.

The second case illustrates jejunal ulcer following gastroenterostomy, gastrojejunal ulcer following gastric resection, and jejunal ulcer following vagotomy.

Case 2.—The patient, a man aged 60, came to the clinic on May 19, 1936. At that visit, posterior gastroenterostomy was performed for perforated duodenal ulcer with hemorrhage. The patient was free of symptoms until November, 1941, when pain and hemorrhage recurred. These symptoms were persistent and continued. On Jan. 17, 1944, the gastroenteric anastomosis was disconnected, gastric resection with posterior Polya-type anastomosis was performed, and jejunojejunostomy was carried out for acute jejunal ulcer.

Periodic attacks of pain with tarry stools began late in 1945, and in October, 1946, the patient had hematemesis, tarry stools, and epigastric pain. On Nov. 21, 1946, transthoracic vagotomy was performed for jejunal ulcer. Pain was relieved, but massive hemorrhages occurred in May, July, and August, 1948. Roentgenograms made on Aug. 13, 1948, revealed evidence of a jejunal ulcer, but roentgenograms made on Aug. 30 and Sept. 3 did not show it. Results of insulin tests were abnormal on Aug. 17, 1948, normal on Aug. 26, and abnormal on Sept. 3.

The patient returned May 5, 1950, because of melena and hematemesis. He had had no ulcer pain. An insulin test on May 26 gave an abnormal result, and the concentration of free hydrochloric acid varied from 12 to 80 (Töpfer's method) during the insulin test. On June 2, 1950, the gastrojejunal anastomosis was disconnected, a portion of the jejunum containing the ulcers was resected, and end-to-end jejunojejunostomy was performed. Further resection of the stomach, with an anterior Balfour-Polya type of anastomosis and bilateral transabdominal vagotomy, was performed. The insulin test on June 2 gave a normal result and the concentration of free hydrochloric acid in the gastric contents varied from 0 to 8 during the test.

After this operation the patient had no more gastrointestinal disturbance or gastrointestinal bleeding, but he died Dec. 18, 1950, from cerebral hemorrhage.

Since vagotomy is so effective in the treatment of recurring ulceration after gastric resection, the question is frequently asked: "Why is not vagotomy added to gastric resection to prevent recurring ulceration?" Druckerman, Weinstein, Klingenstein, and Colp[12] have recently reported 385 consecutive cases of duodenal ulcer, in 220 of which only gastric resection was performed and in 165 gastric resection with vagotomy. Whereas a recurrence rate in the former group was 4.5%, with an additional 1% of cases in which recurrence was suspected, no recurrences had developed to date in the group in which vagotomy was performed with gastric resection. It must not be forgotten, however, that in the experience at the Mayo Clinic the average interval between gastric resection and the development of gastrojejunal ulcer has been approximately three and a half years. Druckerman and co-workers [12] have not stated the nationality or race of their patients, that is, whether most of them were Jews. They reported that postoperative morbidity and complications were about two and one-half times greater in the group subjected to vagotomy. This was due to an increase in postoperative pulmonary complications, diarrhea, and vomiting. Of their 218 traced patients who had undergone resections, 195 were well and 8 improved (93%), while of the 161 traced patients who had undergone resection and vagotomy 156 were well and 2 were improved (98%). Prolonged moderate diarrhea occurred in 7% of the cases of the latter group after the combined operation.

---

[12] Druckerman, L. J.; Weinstein, V. A.; Klingenstein, P., and Colp, R.: Duodenal Ulcer Treated by Subtotal Gastrectomy With and Without Vagotomy, J. A. M. A. 151: 1266-1269 (April 11) 1953.

Because of the persistent troublesome disturbances in motility and the lower recurrence rate of 2% after gastric resection alone for duodenal ulcer at the Mayo Clinic, we do not perform simultaneous vagotomy and gastric resection except in selected cases. The patients selected for this procedure, as recommended by Johnson and Orr,[13] have unusually high concentrations of gastric acids or hereditary racial characteristics that indicate that they might be candidates for recurring ulceration.

Since vagotomy is effective in preventing recurrences of ulcer after resection, the question that immediately follows is: "Why isn't vagotomy effective in preventing recurrences after gastroenterostomy?" Unhappily in our experience, and in that of some others, vagotomy has not prevented recurrences in some cases; for example, Crile reported recurrence in 6% of 400 cases, Pollock [14] in 8% of 462 collected cases, and Hoerr [8] in 12% of 146 cases from the Cleveland Clinic in 1953. Probably the reasons for this are that the hormonal influence of the pylorus remains, the stomach retains food longer, and a greater quantity of acid is secreted and retained within the stomach. Evidence of this is the higher incidence of relative achlorhydria in the resected stomachs (72%) as compared to 34 to 36% of the patients who had gastroenterostomy and vagotomy. It seems logical, therefore, to assume that the rate of recurrence of ulcer would be lower after resection.

COMMENT

We would not close this discussion without emphasizing that in the treatment of gastrojejunal ulcer, especially after gastric resection, vagotomy is an operation that produces amazingly fine results in about 70% of cases at the extremely low operative risk of about 1% and that these results are far superior to those of reresection. In a few cases it has been necessary to combine further resection to almost total gastrectomy with vagotomy to prevent recurrence of ulcers.

One of us (W. W.) has used vagotomy combined with gastroenterostomy for middle-aged men who had high concentration of acids and large duodenal ulcers when the risk of removal or allowing them to remain as a part of a gastric resection was high. Under these circumstances the results from both our standpoint and the patient's have been satisfactory. In similar cases gastroenterostomy without vagotomy has been oftenest employed relatively satisfactorily. In neither case, however, have the results from all standpoints been equal to those of the average of other patients on whom gastric resections were performed by the various surgeons operating on patients with peptic ulcer at the Mayo Clinic. For this reason we and our colleagues at the Mayo Clinic have favored gastric resection in the treatment of chronic duodenal ulcer when operation was indicated and when resection could be done safely. We have continued to use gastroenterostomy and gastroenterostomy with vagotomy in cases in which gastric resections seemed to carry an unreasonable risk when compared to that of gastroenterostomy. The so-called exclusion operation, in which the pylorus is allowed to remain even though the mucous membrane is removed in the course of gastric resection, is practically never used at the clinic for large duodenal ulcers because of the high incidence of gastrojejunal ulcers reported by others when the pylorus is left.

Excellent summaries of large series of cases of peptic ulcers have appeared in 1952 in the *Lancet* by Pulvertaft,[15] Johnson and Orr,[13] and Pollock,[14] and in the *British Medical Journal* by Ogilvie. These bear out our conclusions and are recommended as very interesting reading.

Laboratory Tests vs. Stethoscopes.—You might find it strange that I, as a pathologist, should be asking for a reduction in the number of laboratory tests. I believe that in the cases of difficult and unusual problems any amount of laboratory work is justified, but unimportant testing in the general run of cases is a waste of the laboratory worker's life, and the time spent performing this almost useless work might better be devoted to the serious diagnostic problems. I feel strongly that the routine ordering of tests should be abolished. . . . The modern laboratory aids encourage careless bedside study. I find physicians who shout for icterus index reports, yet have never lifted the eyelids of the patients; who speak glibly of hemorrhage from the stomach and bowel, but who have never looked at the stool or gastric vomitus. It is quite common for these very dark items to be mistaken for blood by nurses who chart them as hemorrhage. I find the practitioner timid about suggesting Addison's disease in the presence of weakness, anemia, emaciation, skin bronzing and very low blood pressure until he knows the sodium and potassium values or the output of 17-ketosteroids. Did Addison have such a test? Did Graves have basal metabolism reports? While the B. M. R. is interesting, it is border-line in many non-toxic thyroid cases and scarcely more informative than checking the pulse rate.—E. Kellert, M.D., Laboratory Tests vs. Stethoscopes, *American Practitioner and Digest of Treatment*, July, 1953.

MANAGEMENT OF THE PREGNANT DIABETIC

Edward Tolstoi, M.D., William P. Given, M.D.
and
R. Gordon Douglas, M.D., New York

In 1950 we published the results of 131 pregnancies in 106 diabetic women. These were obtained from the hospital records and represented the work of various members of the staff.[1] The data revealed that toxemia was present in 48% and ketosis in 16.8% and that over 50% of the babies were over size as judged by the average clinic weight of 3,450 gm. Our total fetal loss was 30%. This included 10 spontaneous and 4 therapeutic abortions, 4 immature infant deaths, and 1 ectopic pregnancy. Our fetal mortality was 24.8% consisting of 6 premature and 22 mature infants. It was our conclusion that the toxemia, ketosis, and excessively large fragile infant were the principal causes for our fetal loss, and no doubt our lack of knowledge concerning other intangibles was a contributing factor. Since the pregnant diabetic presents a number of problems, we reasoned that the management of these patients by a group—each member devoted to his field—might be more effective and productive of better results. We were influenced in this respect by Priscilla White whose clinic is so organized. Consequently, such a group was established, and space was provided in the Women's Clinic of the New York Hospital, where all of us could work together at the same hours and be available for the discussion of any problems that arose. This paper reports our procedure and the results with 72 cases treated during the past three years.

ANTEPARTUM CARE

Most diabetic women before assuming the responsibilities of motherhood want to know *(a)* whether pregnancy is safe for them, *(b)* what the chances are for a living baby, and *(c)* whether the child will have diabetes. On the basis of our experience, we tell the patient that the healthy diabetic runs no greater risk to herself as far as her life is concerned than the nondiabetic and that she has an 80% chance of having a living baby. As to the possibilities of diabetes developing in the child, we can only quote the work of others that the inheritance of diabetes follows the Mendelian laws.

After the initial examination and as soon as possible after conception, the internist and the obstetrician jointly examine the patient every week. At each visit the patient is weighed, and the abdomen is palpated to determine the size, presentation, and position of the fetus. The height of the uterus is noted. The fetal heart sounds are sought, and their character is recorded. The blood pressure is taken, the eyegrounds are studied, and the extremities, as well as the abdominal wall, are examined for edema. The urine is examined weekly for albumin, acetone, and sugar. We have drawn blood weekly for various investigations. No hormones were used. Because of the tendency of the pregnant diabetic toward fluid retention and clinical edema, patients were given 6 to 8 gm. of ammonium chloride daily for four days of each week. In addition, we restricted the salt intake by asking the patient not to use salt in her cooking or at the table. The latter procedures were recommended at the 16th week.

The diabetes was treated by the clinical method. The patient is permitted a self-selected, unweighed, and unmeasured diet to suit her taste and appetite. Dietary restriction was urged in the overweight or when there was rapid gain in weight. Optimal weight gain should be the same as for the nondiabetic patient. With this liberal diet we usually prescribe one daily dose of isophane (NPH) insulin or occasionally a mixture of regular and protamine zinc insulin in quantity sufficient to: *(a)* maintain the patient free from the symptoms of diabetes (thirst, frequency, nocturia, and polyuria), *(b)* maintain or induce the gain of small amount of weight, and *(c)* keep the urine acetone-free.

In order to determine the optimum insulin dosage, we question the patient as to the presence of symptoms of diabetes or those of hypoglycemia, and, if the former are present, we increase the dosage by 5 units until the symptoms disappear. On the other hand, if hypoglycemic symptoms are present, the insulin is lowered by 5 units until they clear. The insulin requirements are different for each patient, and it has been our experience that, as a general rule, they increase with the progression of the pregnancy. Our studies have shown that the absence of the symptoms of diabetes is a dependable criterion, per se, of control. Since we obtained blood at weekly intervals for certain investigations, we determined the fasting blood sugars also, and it is of interest to note how closely they approached normal values when the clinical criteria for control were achieved.

Provided no complications develop the patient is followed in this manner until about the 35th week of her pregnancy, and then she is admitted for the evaluation of the type and time of delivery. Roentgenograms of the patient's abdomen and pelvis are made. Also, an attempt is made to estimate the size of the infant. This has proved difficult at times because of the edema of the abdominal wall or the presence of a large amount of amniotic fluid. (It may be generalized that about 50 to 60% of the patients will be delivered prematurely by cesarean section, as this appears the most practical method of delivery.) Spontaneous labor and vaginal delivery in the healthy diabetic are permitted when *(a)* there is no cephalopelvic disproportion, *(b)* a short labor is anticipated, *(c)* obstetric conditions indicate the patient is ready for labor, and *(d)* diabetes is of short duration.

From the departments of obstetrics and gynecology and of medicine of the New York Hospital and Cornell Medical College.

Read before the Section on Obstetrics and Gynecology at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

[1] Given, W. P.; Douglas, R. G., and Tolstoi, E.: Pregnancy and Diabetes, Am. J. Obst. & Gynec. 59: 729, 1950.

LABOR

During labor the patient is given 5% dextrose in water intravenously at the rate of 2,000 cc. every 12 hours and 1 unit of regular insulin for every 2 gm. of sugar in the infusion. The urine is examined at hourly intervals for acetone and sugar. If only acetone is present more dextrose is given. If both sugar and acetone are present, more insulin is given depending on the qualitative reaction for dextrose, usually 25 units for a 4 plus and 15 units for a 2 to 3 plus. Glycosuria alone is not treated. Analgesic agents are used sparingly, as the infant of a diabetic mother is often immature despite its size and tolerates respiratory depressants poorly. General anesthesia has been avoided. Low spinal and pudendal block are preferable. Wide episiotomy and low forceps are recommended.

COMPLICATIONS

There are four complications to which the pregnant diabetic is specifically exposed. These are preeclampsia, progression of hypertension with the development of albuminuria and retinopathy, hydramnios and edema without hypertension, and ketosis with or without acidosis. Death of the infant in utero may occur with any of these complications, and, though they may occur at any time in the pregnancy, they are most frequent after the 30th week. We have been impressed by the sudden need for more and more insulin to keep the patient ketone-free. Whereas a certain dosage sufficed prior to the 30th week, it was definitely inadequate after, and the insulin dosage had to be increased at times to twice the amount to obtain an acetone-free urine. Whenever any one of these serious situations appears, the patient must be hospitalized. The ketosis, although we regard it as a real emergency, offers no problem. A precipitating cause is sought. If it is due to an infection, appropriate antimicrobial therapy is instituted and the ketosis itself is treated as follows: 1. The urine is examined every half hour for sugar and acetone. If necessary, a catheter is inserted into the bladder, thus facilitating the collection of urine. 2. Twenty-five units of regular insulin are given every half hour as long as acetone continues to appear. The administration of insulin is continued until three consecutive acetone-free urines are obtained. 3. Fluids, such as fruit juices, water, milk, and broth, are given by mouth as tolerated whenever practical. 4. If the patient cannot retain or take fluids, an infusion of 5% dextrose in water is given at the rate of 2,000 to 3,000 cc. every 24 hours.

Usually with this technique of combined therapy both the infection and ketosis respond and the patient may resume her usual diabetic regimen. Unfortunately, we have no specific therapy for preeclampsia, hypertension, and hydramnios. Consequently, our treatment is empirical; it includes bed rest, sedation, and salt and fluid restriction. We follow the height of the fundus, estimate the tenseness of the abdomen, and measure the abdominal circumference to determine increases in amniotic fluid. For such increases we have given meralluride (Mercuhydrin), and, though in an occasional case the result was quite dramatic, it was by no means consistent. Recently, Nelson, Gillespie, and White[2] have suggested withdrawing some of the amniotic fluid. It seems that nothing can be predicted from all this empiric and unsatisfactory therapy, and one can do no more than hope that the infant will not die in utero until delivery can be accomplished. The only real cure as far as we are aware is the termination of the pregnancy.

If any of these complications occurs between the 30th and 32nd week of pregnancy, one is confronted with a most difficult decision. In considering delivery, one must weigh the dangers of prematurity against those of intrauterine death. We have been unable to set a definite time for delivery; each patient must be evaluated individually. During this most critical period, the patient with complications is observed very carefully and frequently. Ambulatory care is unsatisfactory. The fetal heart sounds are listened for, and the patient is questioned as to the degree of motility of the infant. As long as these are present delivery is postponed in the hope that each additional day or week will provide a more mature infant. However, when there is appearance or increase of retinal hemorrhages, progression of the toxemia, and/or an increase in the amniotic fluid, the patient is delivered promptly, usually by cesarean section.

The problem of management is most difficult between the 32nd and 34th week. Prior to the 32nd week, the infant is often not viable; consequently not much is to be done. After the 34th week, the problem of when to deliver is not as difficult when toxemia, hydramnios, or hypertension with progressive vascular changes are found. The patient is delivered without any delay, usually by cesarean section. While this offers the best chance for a viable infant, it is by no means a guarantee; thus, de-

livery should be achieved in the diabetic whose pregnancy is complicated by toxemia, hydramnios with edema, and hypertension and progressive retinal changes. After the 34th week there is little gained in waiting, and a chance for a viable infant may be lost by delay. It may be stated that cesarean section is the method of choice in delivering an excessively large infant or a breech regardless of any complications.

CESAREAN SECTION

Cesarean section is done with the patient under local anesthesia. During the operation, the patient is given 1,000 cc. 5% dextrose in water intravenously, and after about 250 cc. have been given 25 units of regular or crystalline insulin are given hypodermically. If desired, the insulin may be given in the infusion. When the operation is over, a retention catheter is placed in the bladder and the diabetes is treated on the basis of the results of the urine examinations for sugar and acetone done at two hour intervals. If both sugar and acetone are present, regular insulin is given in doses determined by the glycosuria. A 4 plus specimen calls for 25 units and a 2 to 3 plus for 15 units; a negative sugar specimen must be covered with 200 cc. of orange juice. If the patient cannot take fluids by mouth, a 5% dextrose infusion of 1,000 cc. should be given. Usually, if both sugar and acetone are present postoperatively, the latter clears after two or three doses of regular insulin, and, if there is no thirst, the glycosuria is not of any concern. The catheter is removed 24 hours postoperatively, and the patient is offered food to suit her desire. The predelivery type of insulin dosage is reduced by 25 to 50%, and the optimum amount is then determined by the patient's symptoms. If she has symptoms of diabetes, the insulin is increased by 5 units every three days until the symptoms disappear. If, however, the patient has insulin reactions, the dosage is reduced by 5 units the next day, and this reduction continues as long as reactions occur. An asymptomatic glycosuria is disregarded, and we wish to emphasize that, in spite of a continuous glycosuria postoperatively, the wound healing was no different from that of a nondiabetic patient. We have had no infected wounds.

THE NEWBORN

Infants born to diabetic mothers are frequently of excessive size; their activity is poor; their cry is weak; and their respirations are at times established with difficulty. The babies may reveal a brawny generalized edema, cyanosis, icterus, and dyspnea. A roentgenogram often shows cardiac enlargement, and, though the blood cell count is normal, nucleated red blood cells may be found. Among these infants there is a high incidence of atelectasis and pneumonia. Intracranial hemorrhage is common. The livers are apt to be enlarged. The blood sugar values may have a wide range but are not different from the values of infants born to nondiabetic mothers. Because these infants are so fragile, they are treated as premature infants regardless of their size.

When delivery is planned a pediatrician is in attendance, and he assumes complete charge as soon as the child is delivered. Our procedure for the care of these infants includes several important aspects. 1. The airway is cleared. Repeated suction at definite intervals is used to clear the air passages of mucus and amniotic fluid. 2. After the passages have been cleared, oxygen is given and the child placed in an incubator with an oxygen inflow. 3. The child is examined and fluoroscopy is done. If the heart is enlarged or the liver is felt a distance below the costal arch, 0.035 to 0.04 mg. per kilogram of body weight of digitoxin is given as a digitalizing dose and 0.0035 mg. per kilogram daily as a maintenance dose. 4. The stomach is aspirated every 3 hours. It is best to keep the stomach as empty as possible so that the child will not regurgitate fluid and aspirate it subsequently. 5. The infant is also given 100,000 units of penicillin and 40 mg. of dihydrostreptomycin per kilogram of body weight every 24 hours. The antibiotics are administered for a week or 10 days. If the child is markedly edematous, fluids are withheld for 24 to 48 hours. And, during this period, there is often a weight loss of 350 to 500 gm. The child is disturbed as little as possible but is examined in the incubator for the character of the heart sounds and liver size. After food is withheld for the first 48 hours, 15 cc. of 5% glucose is given by nipple if the baby will take it, otherwise by stomach tube. Often the latter method is used as these babies eat poorly. They also tend to be inactive. About one or two days of feeding with glucose, depending on how active the child is, is followed by one-half skimmed or skimmed milk formula in 10 cc. quantities every 3 hours. The skimmed milk feedings are continued for two or three days, and then an evaporated milk formula is prescribed. This is made up of two parts of water and one part of evaporated milk and 5% Dextri-Maltose no. 2 (salt-free) containing about 70 calories per 100 cc. The fluid replacement is the same as for a normal infant, that is, 100 cc. per kilogram of body weight by the third day and 150 cc. per kilogram by the seventh day.

The child is observed frequently. If it is active and eats well, it may be removed from the incubator for a short period. If its color, activity, and respirations remain good, the periods out of the incubator may be increased until the infant can be removed from it entirely. The duration of incubation varies with each baby and depends chiefly on its reactions outside of the incubator. Usually, the active babies who eat adequately do not need long care in the incubator. It must be appreciated that this plan is subject to modification, because of ever-changing conditions. If one has guidance to some definite procedures, however, he can follow them until his own experiences and judgment dictate otherwise.

RESULTS

At the time this report was prepared, 72 patients had been treated. All of the mothers are alive. Twenty-four, or one-third, have had diabetes for over 13 years. The total and neonatal fetal losses are summarized in table 2.

It is significant that, of the infants lost, the mothers' course was complicated by one or more of the four complications shown in table 3. Furthermore, when any of these complications occurred, and that was frequently, the delivery was affected in one of the four manners shown in table 4.

COMMENT

From the results reported by other workers in this field, the total fetal wastage is about the same. The greater differences in figures are among the viable fetuses. Nelson, Gillespie, and White[2] have a 10% loss of fetuses over 28 weeks of gestation; Reis, De Costa, and Allweiss,[3] 13.6%; Miller,[4] 14.7%; Hall and Tillman,[5] 18.3%; Pedowitz and Shlevin,[6] 20.7%; and ourselves,[1] 22.2%. There are many other reports, but we have limited our discussion to those having a viable fetal mortality of 25% and less.

In the treatment of these patients, there were areas of agreement and disagreement among the various workers in matters of technique and methods of reporting. Placing these factors in sharp focus may be clarifying. All workers agree on several points. 1. Ketosis and ketoacidosis must be avoided and, when present, treated vigorously. 2. Premature termination of the pregnancy as a rule is advisable, often by cesarean section. All are aware that, though this procedure is no guarantee for a viable baby, it frequently offers the best chance. 3. Skilled pediatric care is necessary in the neonatal period, especially with particular understanding of the treatment of the premature infant.

The areas of disagreement are (*a*) the use of hormones, (*b*) the classification of the severity of the diabetes, (*c*) the type of diabetic care, and (*d*) the evaluation of results. With so many variables; there are bound to be differences of opinion, and the better results are attributed to the particular techniques employed. Thus, Nelson, Gillespie, and White,[2] the only group that used hormones, consider them a valuable contribution to a greater fetal salvage. Their loss was only 10%. Reis and his associates[3] and Miller[4] used no hormones, and these workers reported losses of 13.6% and 14.7%, respectively. Our results are not so good in view of the fact that we had a perinatal mortality rate of 22.2%. We did not use hormones. At first glance this difference is quite striking, but it is more apparent than real. Nelson, Gillespie, and White[2] eliminated 14 patients from their viable group because of therapeutic abortions done for preexisting retinal and renal disease. We did not exclude such patients, as we performed no therapeutic abortions. Indeed, we were fully aware of the poor prognosis, and when occasion indicated we placed the issue frankly before the prospective mothers. Since they wished to carry on, we acquiesced. As expected, though some of the babies were viable, they died shortly after birth. These were losses, and they were so recorded. As to the classification of the diabetes, what is severe diabetes? Is it a diabetic who goes on for years requiring 15 to 20 units of insulin for satisfactory regulation by any accepted technique and who develops retinopathy and other manifestations of diffuse vascular disease? Is it the diabetic without vascular disease who requires 50 to 75 units, or more of insulin to avoid ketosis? Then again, how would one classify two patients of about the same age and duration of diabetes with or without vascular disease whose insulin requirements vary, one requiring 25 units and the other 75? It becomes obvious from such questions that classification is difficult. We agree that vascular disease in a diabetic is a serious complication, but we also submit that the management of diabetes in such cases is no problem. It is a problem, however, in a young patient who has no vascular disease but who has a great tendency toward ketosis and requires large doses of insulin to remain ketone-free. It seems to us that this is the severe diabetic and that, in evaluating the severity of diabetes, some persons have been influenced by the degree and extent of vascular disease. They have been measuring the concomitants or sequelae of diabetes and not severity as judged by difficulty in management.

Induction	11	15.5
Spontaneous deliveries	17	23.6
Cesarean section	37	51.2
Total	72	100.0

As the treatment of the pregnant diabetic is complex, any simplification would be a step forward, provided the results were not sacrificed. Since our total fetal loss is not significantly higher than that of others and since our results were achieved without the use of hormones and with safe practical technique for the treatment of the diabetes, we have adopted the simpler methods. We are not satisfied with our results, however, and are constantly evaluating them and those of other workers and searching for information that will enable us to propose a more definite routine as well as to deliver more living infants.

SUMMARY AND CONCLUSIONS

Infant survival in the pregnant diabetic (comparable to the more favorable results reported) can be achieved (*a*) without hormone therapy and (*b*) by employing the clinical method for the treatment of diabetes. In treating pregnant diabetic women, ketosis must be avoided. This complication is, however, understood and can be treated.

Complications, such as toxemia, hydramnios, and hypertension, in about the 30th week or shortly thereafter are most serious. There is no specific treatment for them.

After the 32nd week, depending on complications, premature delivery offers the best, but by no means certain, chance of fetal survival. The exact time for delivery cannot be determined from any specific or past experience. Cesarean section is the procedure of choice in terminating the pregnancy of the diabetic patient with complications and an excessively large infant. It is the most practical approach but does not guarantee a living child. Experienced pediatric care and treatment of the newborn as a premature infant is imperative.

IS STELLATE GANGLION BLOCK OF VALUE IN STROKE?

J. Eugene Ruben, M.D.
and
Robert A. Mayer, M.D., Philadelphia

Millikan, Lundy, and Smith and Alvarez[1] have suggested that stellate ganglion block is of no value in patients suffering cerebrovascular accident. Previous reports disagree with this point of view.[2] Because of the doubt cast by these reports, we consider it timely to report our experience as a means of stressing the value of this therapeutic measure in stroke.

In 1947, one of us (J. E. R.) began to do stellate ganglion blocks on stroke patients. By 1949, we had accumulated sufficient experience and had seen enough good results following this therapy to be interested in a controlled study. An arrangement was made by which every other patient admitted to the neurological wards of the Philadelphia General Hospital with a diagnosis of cerebrovascular accident could be subjected to stellate ganglion block as often as indicated. In April, 1949, 37 such patients were admitted. Ganglion blocks were effected in 18 patients, and, of these, 9 (50%) left the hospital alive, and the other 9 died. Of the 19 patients who did not receive blocks only 5 (26%) left the hospital alive. The series was too small to be statistically significant, but the results were so encouraging that mortality data on patients admitted during the same period in 1948 (when no blocks were done) were obtained for comparison. In 37 consecutive admissions 8 patients (22%) left the hospital alive. In this series of cases we took the death rate of stroke patients in the hospital as a yardstick, and the figures heavily favor the treated cases.

The treated cases in the 1949 series were included in a previous report[3] of 100 cases of stroke treated by stellate ganglion block. Since that time an additional 58 patients with apoplexy have been treated with stellate block. These were consecutive, referred private patients, 43 of whom had conditions of less than one month's duration, and were, therefore, considered acute. The other 15 were first seen more than one month after the ictus and were classified as chronic.

Tables 1 and 2 give data on these 58 patients. Among the 43 acute apoplectic patients, cerebral thrombosis was both the commonest and the most responsive of the causes of cerebrovascular accident. Hemorrhage is poorly represented, because patients in whom gross hemorrhage is suspected are never given immediate block. Patients with encephalomalacia respond very poorly to stellate block or any other therapy, and the results bear this out. It is extremely difficult to define "improvement" in these patients accurately except when it is dramatic. Of the 17 with thrombosis, 11 had dramatic improvement; 2 of the 4 with embolus and all with spasm had dramatic results. Of the 26 who improved in the series, 69% showed dramatic improvement following the block. We have had the discouraging experience of having as many as 10 consecutive patients show no improvement. Fortunately, this occurred only after we had had some good results. Stellate block appears effective beyond coincidence or suggestion when a patient moves a previously flaccidly paralyzed extremity within a few minutes of the appearance of Horner's syndrome.

REPORT OF CASES

Case 1.—A 64-year-old white woman was stricken with left hemiplegia with a complete flaccid paralysis and almost complete left hemianesthesia on July 30, 1951. Right stellate block was done on August 1, and, within five minutes of the appearance of a right Horner's syndrome, she was able to perform gross movements of the left arm and leg. The following day the block was repeated, and fine movements of the left fingers were possible immediately afterwards. She was gotten out of bed. On August 3, the final block of the right stellate ganglion was done. Five minutes after this was completed, the patient could perform any desired movement of the left side of the body, and sensation was normal. She was discharged five days after admission, to resume her normal activities without further treatment.

Case 2.—A 61-year-old hypertensive white man awoke on May 1, 1952, with paresis of the left face and arm and flaccid paralysis of the left fingers. Right stellate ganglion block was done, and immediately after the appearance of a right Horner's

syndrome motion returned to the left third, fourth, and fifth fingers, and the weakness of the left face and arm lessened. The patient improved in the next 24 hours; the right stellate block was repeated, and he could then move all fingers of the left hand. In the next 24 hours there was some regression, but repetition of the block was followed by a dramatic improvement. The block of the right stellate ganglion was repeated two more times in the next four days. After this the patient had only some clumsiness in the movements of the fingers of the left hand. This disappeared in the following week, and he was discharged without residual effects two weeks after the ictus.

* Block effected more than 24 hours after hemorrhage.

Case 3.—A 60-year-old white man with mitral stenosis and auricular fibrillation had sudden, complete right hemiplegia with total dysarthria on Nov. 5, 1952, at 10:00 p. m. A diagnosis of cerebral embolus was made, and he was admitted to the hospital the following morning. At 4:00 p. m. on November 6, he had total right flaccid paralysis, dysphagia, unintelligible dysarthria, right mass withdrawal reflex, and equivocal right Babinski reflex. The right side of the face was weak, the tongue protruded to the right, and the patient was semistuporous. Ten minutes after left stellate ganglion block, which resulted in a prompt Horner's syndrome, the patient became conscious and had gross movements of the right arm and leg. In the next 24 hours, he showed no further improvement. The block was repeated, and fine movements returned immediately to the right fingers and toes. After four more left stellate blocks in the next 16 days, the patient was able to walk with help on November 24. By November 30, he was able to walk alone in the walker and was practicing writing. On December 5, he was able to walk without a cane and could speak a few words. He was discharged from the hospital December 12. A total of nine left stellate blocks had been given during his five weeks of hospitalization. On Jan. 7, 1953, the patient was doing limited work, was able to write well enough to sign checks with his right hand, could make himself understood, and could care for his personal needs.

There are those who maintain that such results might have been obtained without stellate block. But we wish to emphasize that in these cases, and in many others, dramatic improvement was observed almost immediately after the appearance of Horner's syndrome induced by stellate ganglion block.

The use of stellate ganglion block in the patient who has had a stroke is based on the theory that there is an element of reflex cerebral vasospasm associated with the vascular insult. If this spasm is prolonged, the resulting ischemia may impair the function of a greater area of brain tissue than that affected by the vascular lesion. On this basis, stellate ganglion block is of most benefit when effected early. If the vascular injury involves a vessel so large that massive cerebral infarct occurs, stellate ganglion block will be of no value. But if it involves only a small vessel, abolition of the reflex vasospasm may preserve an area of brain tissue that might otherwise be permanently damaged. Since there is no way of distinguishing immediately after the ictus whether the vascular insult is in a large or small vessel, every patient with a stroke not caused by hemorrhage deserves a therapeutic trial with stellate block. It is our practice to effect at least three blocks at 24 hour intervals before concluding that a patient will not be benefited.

For some unknown reason, a few patients respond to block months or years after the ictus. On this basis 15 chronic hemiplegic patients have been treated with stellate ganglion block, and these results are given in table 2.

Case 4.—A 60-year-old white man had a cerebral thrombosis in July, 1952. He was immediately hospitalized and treated conservatively (but without stellate block) for three weeks. This led to a stabilization of his general condition but no improvement of the hemiplegia. He was discharged with total right flaccid paralysis. When he was examined on September 15, there was a complete flaccid paralysis of the right arm and leg and right facial weakness, including the tongue and eyelid. His speech was markedly impaired by aphasia and dysarthria, and he complained of severe pain in the right shoulder.

After left stellate ganglion block and the appearance of a left Horner's syndrome, the pain in the right shoulder stopped, and the patient was able to move the right leg slightly. Corrective exercises were recommended, and potassium iodide was added to the ascorbic acid, rutin, and phenobarbital that he had been taking. At the end of two weeks and after five stellate ganglion blocks, he had sufficient power in the right upper and lower extremities to stand in a walker and to manipulate the device with help. One month after treatment was begun, he had added abduction and adduction of the thigh to extension of the leg on the thigh, and rotary motion of the shoulder appeared earlier. He was fitted with an ankle brace to prevent inversion of the foot and walked without aid. Two weeks later (after 12 blocks) the patient was able to flex the right arm at the elbow. Appropriate and progressive corrective exercises were prescribed and taught at each stage of improvement. Electric muscle stimulation was begun after the first month of treatment, along with indicated physical therapy. In seven weeks, he was able to walk with a cane, and one week later he was walking to the dining room for his meals. Maximum improvement from stellate block therapy was reached after 22 blocks in four months. At this time the patient was able to go up and down the steps, dress daily without help, and walk unaccompanied.

METHOD

Stellate block in this series was produced by depositing 10 to 20 cc. of local anesthetic solution on the transverse process of the sixth cervical vertebra by the anterior approach after the method described by Pereira.[4] Procaine (1%) or the equivalent concentration of similar drugs was used. The block was repeated at increasing periods of time until the patient showed no further improvement after a successful block. In six years of using this block by the method described, we have not had a single mortality or any disabling sequelae. We

believe that stellate ganglion block must be combined with other treatment, including general medical support and good nursing care, in the management of the patient who has had a stroke. Encouragement of the patient to build confidence in himself and his physicians is essential. Physical medicine, with its corrective exercises, reeducation, muscle stimulation, and appliances, is important. In the acute phase, any slight degree of cardiac decompensation is significant, and appropriate treatment should be started promptly.

SUMMARY AND CONCLUSIONS

Fifty-eight previously unreported cases of stroke treated to maximum benefit with stellate ganglion block in addition to usual routine management are reported. More than 60% of the persons showed some improvement immediately after the appearance of Horner's syndrome. In almost 70% of those showing improvement, the benefit was striking. Since these were all private, referred patients, their general medical, nursing, and adjunct care was probably above average. This may account for our better than average results.

Increase in muscle power and control has been observed to follow stellate ganglion block in acute cases and less frequently in chronic ones. This increase has followed the appearance of Horner's syndrome (indicating a successful block) in minutes, not hours, after the injection. On the basis of our experience and results, we believe that stellate ganglion block in experienced hands is innocuous and that, until some more definitive therapy is devised, patients suffering from stroke due to embolism, thrombosis, or spasm should not be denied the possible benefits of this therapeutic measure.

MEPERIDINE HYDROCHLORIDE USED INTRAVENOUSLY BEFORE GASTROSCOPY

PRELIMINARY REPORT

Paul J. Cimoch, M.D.
and
C. Wilmer Wirts, M.D., Philadelphia

Most patients undergoing gastroscopic examination are given a barbiturate orally and a narcotic and an antispasmodic-antisecretory drug by hypodermic injection.[1] The dosage and time of administration of these drugs vary widely. Monat,[2] in an analysis of 3,000 cases, studied the effect of morphine, meperidine, and Pantopon (contains the total alkaloids of opium as soluable hydrochlorides) in combination with atropine sulfate and pentobarbital alone as premedication. In conjunction with 2% cocaine topical anesthesia, these drugs were administered subcutaneously or intramuscularly one hour before examination. Pantopon proved most satisfactory, especially in younger persons, while pentobarbital was better in older and less tense patients. Morphine sulfate was next best to Pantopon, although it occasionally produced a severe reaction with chills, and often the patient became so drowsy that examination was not possible. He noted that, with meperidine hydrochloride given intramuscularly, the patients were euphoric, cooperative, and relaxed and that analgesia was obtained, but that, with or without atropine sulfate, it sometimes produced an excessive amount of gastric secretion. Hufford [3] used meperidine intramuscularly in doses of 75 to 100 mg. and noted a combined sedative and analgesic effect manifested by calmness, an increase in the pain threshold, less gag reflex, diminution of smooth muscle spasm, and reduced salivary secretion. Five of the 38 patients complained of dizziness, and one was slightly nauseated; these symptoms, however, disappeared within 20 to 30 minutes if the patient remained at rest. Batterman [4] noted side-effects to the intramuscular administration of meperidine in 25% of his hospitalized patients. Other observers [5] have noted the ease with which endoscopic examinations are carried out when meperidine is used intramuscularly or subcutaneously immediately before the examination.

In a large medical center in which many examinations are performed, there is often disparity in the time of drug administration and the time of examination. This leads to anxiety and uncooperativeness of the patient because the effectiveness of the premedication has worn off, as it was given so long before the examination, or so recently the effective sedation has not yet developed. Such experiences have made many aware of the need for a medicament, short of general anesthesia, that will satisfy the criteria for successful gastroscopic examination, namely, sedation, relaxation, analgesia, diminution of spasm, reduction in the gastric and salivary secretions, and cooperativeness of the patient. Toward this end, the slow intravenous administration of morphine sulfate and methadone hydrochloride has been em-

ployed.[6] Thiopental (Pentothal) sodium [7] and thiopental sodium with curare and intranasal oxygen have been used as general anesthesia; subsequently thyamylal (Surital) sodium was substituted by Atwater [8] for thiopental sodium. By this method it was noted that the anxiety and restlessness of the patient were eliminated and that the examiner was provided with a quiet and cooperative subject. Its use, however, requires the presence of a trained anesthesiologist, because the drug is given to the point of narcosis.

METHOD OF STUDY

Meperidine hydrochloride has been used to supplement general anesthesia for endotracheal intubation prior to the induction of anesthesia,[9] to overcome the bucking reaction to an endotracheal tube,[10] and, intravenously, to obtain pain relief during curare anesthesia.[11] The intravenous use of meperidine hydrochloride for gastroscopy was suggested by one of us (P. J. C.) because of previous experience in obstetrics, based on the work of Roby and Schumann [12] and the later work of Schumann.[13] We have now used it intravenously in 146 patients, the majority of whom were relaxed and cooperative during the examinations. In this group, side-effects were minimal. These patients were observed in four different hospitals, and some of the examinations were performed by trainees under the supervision of one of us (C. W. W.).

Of the 146 patients examined, 115 were inpatients and 31 were outpatients. The group included patients with cardiac, renal, hepatic, or pancreatic disease. All patients were prepared in the same manner. Examination was usually carried out in the morning while the patient was fasting. One hour before examination, 0.4 mg. of atropine sulfate was given subcutaneously, and 15 minutes and 5 minutes before examination a gargle (1.8 ml.) of 2% tetracaine (Pontocaine) hydrochloride was used. With the patient lying on the table, meperidine hydrochloride was given intravenously over a period of one to three minutes immediately prior to examination. The patient was then placed in the left oblique position and gastroscopy performed. The dosage of meperidine varied from 50 to 100 mg. and was based on weight and age; one patient received 150 mg. The drug is diluted with distilled water to a volume of 10 ml. Initially 0.5 ml. was injected and a minute allowed to pass; if the patient did not experience a reaction, the injection was continued over a two minute period. After the examination, patients remained in bed for one or two hours; after that time outpatients were permitted to leave the hospital. After several months' experience with the foregoing method we decided to discontinue the use of the atropine sulfate and the gargle and to use meperidine hydrochloride as the only premedication. The withdrawal of these adjunct medicaments did not detract in any way from successful examination, and, since it eliminated the risk of topical anesthesia and reduced the preparation to a minimum, it appeared to offer additional advantages.

RESULTS

Of the 146 patients examined, 13, or 8.9%, received 50 mg. of meperidine hydrochloride; 18, or 12.3%, 75 mg.; and 104, or 71%, 100 mg. One patient received 150 mg. Fourteen examinations, or 9.5%, were unsuccessful. Cooperation and relaxation were obtained in the majority of patients; side-reactions occurred in 22, or 15.1%, of the patients. For purposes of evaluation the patients were divided into three age groups. The youngest patient was 21 and the oldest 76 years of age.

In group 1 there were 39 patients between the ages of 20 and 40 years. One patient received 75 mg. of meperidine; the others received 100 mg. Side-reactions occurred in 5, or 12.8%, of the 39 patients. Dizziness and euphoria occurred in three patients and nausea alone in two. One patient received 0.1 gm. of pentobarbital one-half hour prior to the meperidine and was oversedated, but this did not prevent satisfactory examination. Examination was unsuccessful in three, or 7.6%, of the patients; in two, lack of success was due to uncooperativeness and in one, unallayed anxiety.

In group 2 there were 64 patients between 41 and 60 years of age (table 1). This was the largest group of the series. One patient received 150 mg. of meperidine; 2, 75 mg.; 2, 50 mg.; and 59, 100 mg. Cooperation and relaxation were obtained in nearly all of the patients. There were nine, or 14.1%, who experienced side-reactions of dizziness, euphoria, and nausea. The one patient who received 150 mg. of meperidine was cooperative but not relaxed, and the gastroscope could not be passed. Six, or 9.3%, examinations were unsuccessful; five were attributable to cardiospasm and one to perforation of the esophagus. The latter occurred in a 48-year-old white man who complained of intermittent eructations of approximately 10 days' duration. He had a history of closure of perforated duodenal ulcer and a severe unexplained anemia. Roentgen studies showed nothing abnormal, and the stool was negative to benzidine. The patient received 100 mg. of meperidine intravenously prior to gastroscopic examination and experienced no untoward reaction. The examiner had no difficulty in introducing the gastroscope, but, during the course of the examination, a 1 cm. perforation of the esophagus occurred just above the cardia of the stomach. Apparently the patient did not experience any acute pain or abnormal sensation when this occurred. The meperidine may have played an important role in the

prevention of the immediate shock often described when the distal end of the esophagus is ruptured.[14] The perforation was successfully closed surgically, and following convalescence further study failed to reveal any factors predisposing the patient to this accident.

In group 3 there were 43 patients over 61 years of age (table 2). This group showed the best response to the drug; most of the patients were cooperative and relaxed. The meperidine was given in smaller dosages with satisfactory effect; 11 patients received 50 mg.; 15, 75 mg.; and 17, 100 mg. There were eight patients, or 18.6%, who had mild side-reactions of dizziness and euphoria; none had nausea. None of the patients who received a 50 mg. dose had any side-reactions. Thirty-nine of the 43 patients were examined successfully. Of the four, or 9.3%, unsuccessful examinations, three were due to some form of obstruction in the lower esophagus; in one patient, this was associated with congestive heart failure, in another with scoliosis, and in a third with a lesion in the cardia of the stomach. The fourth patient had gastric retention resulting from pyloric obstruction.

COMMENT

Heretofore our routine preparation of patients for gastroscopy consisted of an intramuscular injection of morphine sulfate, 15 mg. (0.25 grain), with atropine sulfate, 0.4 mg. (1/150 grain), given 45 to 60 minutes before examination and a gargle of 2% tetracaine given 15 minutes and again 5 minutes before introduction of the scope. Although side-reactions to this premedication were only minimal, it left much to be desired regarding adequate sedation and analgesia, particularly in the more apprehensive patients. Furthermore, since these drugs were usually given to the patient on the ward prior to his being sent to the examining room, it was often difficult to maintain uniformity in the type, amount, and time of administration of the premedication. Finally, although in our own experience no untoward reaction to topical anesthesia has occurred, serious to fatal consequences have been reported.

Table 2.—*Results of Administration of Meperidine Hydrochloride Before Gastroscopy in Forty-Three Patients Between Ages of Sixty-One and Seventy-Six*

		Gastroscopy Successful		Patient's Condition		Side-Effects	
Dose, Mg.	No. of Patients	Yes	No	Cooperative	Relaxed	Dizziness	Euphoria
100	17	15	2	17	16	1	5
75	15	14	1	15	14	2	3
50	11	10	1	10	9	..	..

From our experience thus far, the administration of meperidine hydrochloride for gastroscopy has been found simple, and the resulting sedation and analgesia have been superior to the results we formerly obtained with morphine and atropine. In many patients, the effect was so striking that they appeared to be in a deep sleep but remained cooperative and responded to instructions. The side-reactions of dizziness, nausea, and euphoria actually were so minimal that they can be discounted. We attributed this to the position of the patient, dilution of the drug, and rate of injection. Schumann noted that there were greater side-effects when the drug was injected rapidly and that many of the side-effects subsided when the patient assumed a prone position. Pronounced changes did not occur in blood pressure or pulse rate. Frequently patients commented on the complete sense of relaxation that was achieved so rapidly. This was particularly helpful in the tense patient who was willing to have gastroscopy performed but who asked to be "given something that would knock him out." In essence, intravenously administered meperidine hydrochloride is valuable in gastroscopy because it effectively produces adequate relaxation and analgesia, with minimal side-reactions. Because it is given immediately prior to examination, it permits the type, amount, and time of administration of premedication to be controlled completely by the examiner. Furthermore, since it can be used as the only premedication, it eliminates the risk of topical anesthesia.

SUMMARY AND CONCLUSIONS

We find the intravenous administration of meperidine satisfactory for gastroscopic examination, with or without topical anesthesia and atropine sulfate given subcutaneously. The elimination of the risk of topical anesthesia is an important advantage of this method of preparation. We also note that the optimum effect of the drug is obtained at the desired time; that the older patients are more relaxed with smaller amounts of the drug; and that side-reactions to the drug are mild and occur with equal frequency in all age groups. There were no general reactions. Patients who have a great deal of anxiety toward gastroscopy tolerate the procedure well when this drug is administered. The hazards and requirements of general anesthesia are not encountered when meperidine hydrochloride is used.

ADDENDUM

Since this paper was written, we have examined an additional 110 patients gastroscopically, with meperidine hydrochloride as premedication. Analgesia was satisfactory, and there were no untoward reactions.

Treatment in Caisson Disease.—It was early discovered by the caisson workers themselves that the only remedy for the malady was to re-enter the high air pressure. A recompression apparatus in the form of a medical air-lock is supplied at all caisson works and in all ships engaged in deep salvage. On the appearance of any symptoms the worker is placed in the compressing room, and the pressure is run up to the level at which he has been working when it is usual for the symptoms to diminish rapidly or to disappear. After the recompression the decompression must be carried out very slowly, for the bubbles of nitrogen once formed in the tissues are not easy to get rid of, although they may be kept at a small size by the pressure. A patient apparently at the point of death with cyanosis and coma may completely recover in a few hours by recompression. When symptoms have appeared the decompression should take from five to twenty-four hours. Caisson workers and divers should wear on the lapels of their jackets a metal tablet clearly inscribed with a notice stating both their occupation and the address of their place of work. They should sleep and live close to the medical air-lock in order that they may be near aid during the first hours following decompression.—D. Hunter, M.D., Occupational Diseases with Neurological Symptoms and Signs, *The Practitioner,* July, 1953.

A CIVIL DEFENSE DIRECTOR LOOKS AT THE MEDICAL PROBLEM

J. F. More, Toledo, Ohio

If we accept the premise, as we must, that the primary objective of civil defense under disaster conditions is to save life, the effective organization of our medical resources is imperative. Technical or professional knowledge, however important and precious it may be, is not enough. It must be organized in order that it may be fully utilized. A civil defense director cannot be concerned with technical and professional details of the treatment of casualties. That is the business and the responsibility of the physicians and members of other segments of the combined medical professions. But he is, and must be, concerned with the organization of every particle of the medical resources, with which America is blessed so abundantly. In his mind, the major questions are: Is our plan as perfect as we can make it? Does it provide for the fullest possible utilization of our medical resources? Have we organized or are we organizing these resources now, the hard way, or are we accepting the easy way of planning for post-attack organization, amidst confusion, hysteria, and panic? All these can be formulated in one basic question. Will our program save the maximum number of lives in the first 10 hours, the first day, the first week, or even the first month, of the disaster? The civil defense director's question is not how but how *many*?

In planning for any project, two things must be known as thoroughly as possible. The first is the problem and the second the means or resources available to us for the solution of that problem. In military parlance, this is known as the estimate of the situation, and it is the basic foundation for the planning of every battle and every campaign. It is basic in the training of every staff officer. Reduced to civil defense terminology, this becomes, first, an accurate estimate of the destructive effects of the atomic bomb and, second, a true and complete picture of our rescue resources. There cannot be sound, practical planning without this knowledge.

THE ATOMIC BOMB ATTACK

From research conducted at Hiroshima and Nagasaki, reinforced with data obtained from our own test atomic bursts, we have a fairly accurate estimate of the effects of the atomic bomb. It is true that most of the available information is on the 1-X, or Hiroshima-type, bomb. But from this basic information we are able to calculate the comparative power of destruction of the 2½-X, 4-X, or 8-X bombs. The estimate as to which bomb and how many may be used on a certain city is a part of strategic planning and urban analysis program and could not be considered without lengthy explanation.

Of course, the structural effects alone can do no more than indicate the number of casualties. The determining factors are: 1. The number of persons in the area at the time of attack. Here, time is an important element. The population distribution of any city varies greatly from day to night. The downtown area of a city may contain one-quarter or more of its population during business hours and only an extremely small percentage at night. Information on population concentration of every major city is available for business hours and residential distribution. 2. The status of advance warning. This is, perhaps, the most important element in the protective functions of civil defense. There is an army axiom that the first requirement of defense against aerial attack is an adequate warning system. This applies with equal force to civil defense. 3. Shelter program. This is, perhaps, the weakest link in the entire civil defense program. Yet, in each city, there are a number of buildings that would provide acceptable shelter. Some of our largest cities have subways. And we are now beginning to have a sound family shelter program. 4. The status of public education in the principles of self-protection. 5. Geographical layout of the city. Terrain features and even the shape of the congested zones could materially influence the effects of the bomb; for example, the casualties in Nagasaki were about one-half of the number of Hiroshima, owing almost entirely to physical layout and terrain feature differences of the two cities.

Knowing these factors, once we locate ground zero, or the ground point under the center of the blast, and the size of the bomb is estimated, we can calculate the estimated number of casualties. For medical planning purposes, we should select a number of probable aiming points and calculate the number of casualties for day and night distribution of population and for various sizes of bombs. Regardless of our resources, each time we do this we find the results staggering in both the tragedy and the enormity of the task that would confront the medical profession in the event of attack.

It is significant that unless there is a daytime attack and the bomb is burst over the business district or some concentrated industrial area, the size of the city does not substantially affect the number of casualties from identical bombs. With some differences, the concentration of population in our cities does not vary with size. In other words, the residential distribution of population follows approximately the same pattern. Generally, cities with larger populations cover correspondingly larger ground areas. Medical resources, however, are rather well distributed on the basis of population. Consequently, a city of 300,000 has a far greater medical problem than one 3, 4, or 10 times its size.

We must know the number of available physicians, dentists, nurses, pharmacists, nurses' aids, laboratory technicians, first aid workers, and other medical personnel, speaking in the broadest category. The available facilities, equipment, and supplies must also be determined. In addition, it is necessary to know how much equipment and supplies can be purchased with the funds governments at all levels are willing or able to provide and how much assistance in both personnel and supplies the neighboring communities could furnish. The help that could be expected from other civil defense services, particularly fire, transportation, warden, engineering,

---

Director of Civil Defense, Toledo.

communication, and police must also be estimated. Information on these resources is available. It is a part of the urban analysis program.

The next step is the actual planning. Here the human factor enters. All persons do not think alike, and planning loses much of its systematic nature. It becomes also an art. So we plan differently, influenced not only by our academic training but also by practical experience in actual or related matters, and by our observations. Either theory or practical experience, or both, can be used as the basis for planning. The plan arrived at may be a slipshod, poorly mimeographed piece of administrative bulletin, or it may be a beautifully executed document. I know the painstaking care, the concentration, the research, and physical and mental energy required to produce an above-average plan, and I have experienced the jubilant fever of achievement. But a plan must be implemented, and implementation means organization.

Organization is a pre-attack and not a post-attack objective. I have heard of plans of assembling personnel after the attack in prearranged areas and then organizing them into teams. One can imagine the magnitude of confusion that would prevail even under the best imaginable conditions following an atomic attack. Is it not stretching the imagination even to consider that we could organize our professional personnel into teams or units under such conditions? The time element must also be considered. Medical assistance must be given to the seriously injured as quickly as possible.

Our medical profession has become highly specialized, yet, under disaster conditions, each physician must be able to care for the seriously injured, at least in triage operations, regardless of the type of wounds. Our medical committee believes that briefing of physicians, at least in the triage phase of operations, is necessary. This applies also to other professions. But, notwithstanding this premise, we must realize that our medical resources are so limited that alone they could not operate effectively. They must be backed by many times their numbers of trained and organized lay volunteers.

We Americans have a rather peculiar and highly valuable characteristic. We like to organize. Even if we hold a small meeting, we have it on an organized basis. And our striving for perfection and our program of mass production of almost everything have made us realize the great value of training. If we hire persons, whether to run a drill press, operate a typewriter, use the tools of any trade, or even to dig a ditch, we want those who are trained. If we believe that training and organization are necessary in the ordinary pursuits of life, can we require less in the tremendous task of saving human life?

To cite a military parallel, what would happen to a field army if the commanding general had only a relatively few highly trained officers, with the rest of his forces untrained, or if he had all the men he needed but they were not organized? If he attempted to organize them after he was attacked, the result would be chaos and panic and inexcusable slaughter.

To expect less than that if we were to meet an atomic attack without training and organization is like a fantastic dream. Our medical resources are so limited within the concept of estimated requirements in an atomic disaster that the highest type of organization, providing for the most efficient utilization possible of our professional personnel, supplemented with trained auxiliaries, is imperative if we accept the principles of our American heritage that human life is the most precious possession of our nation.

The simplest method in planning and organization is to follow established procedures. We know that our army system of evacuation is the most advanced in the world, as was well proved in World War II and again in the Korean campaign. In civil defense, however, there is no similarity of problem nor of resources.

First, the carnage of an atomic blast on a city would make even Napoleon's debacle at Waterloo or the British tragedy at Dunkirk seem like a minor catastrophe. Within the capabilities of field weapons so far used, a 10% loss in 24 hours of battle is a generous estimate. In an atomic attack on a city the casualties could run from 25 to 50% of the population, not in 24 hours but in 24 minutes or less.

In the field we have highly trained, disciplined and organized units, fully equipped to carry out battle or campaign objectives. Teamwork is developed to a high degree of perfection, and even in the confusion of battle there always is control. In civil defense there may be training and organization, but all on a volunteer basis. Discipline can come only through the highest development of volunteer leadership and service. While an army unit has a medical table of organization to care for the maximum number of estimated casualties, even our largest cities cannot hope to provide sufficient professional medical personnel for the adequate care of the number of casualties that we must envision under atomic attack. The Army also has the required equipment and supplies and facilities to meet estimated casualty requirements. In civil defense, we cannot even dream of such abundance of supplies, equipment, and facilities.

Even in World War II, now considered a long time ago, all our wounded had excellent care. We had highly trained and specialized surgical teams almost up in the front lines. Farther back we had field hospitals, then mobile evacuation hospitals and the fully equipped general or base hospitals. Aside from those, we still had the great hospitals in this country. Collection and evacuation of the wounded, always through professional medical channels, was extremely rapid, orderly, and definite. In civil defense such organization in depth is just not possible. In the field we have only one front line; in civil defense every major city could be its own front line within a few hours! There might be no place to fall back and little or no reserves to call on.

In civil defense equipment and supplies, we as a people have adopted the most parsimonious economy that we have ever applied to any part of our national structure. For four years, including the current fiscal year, Congress has appropriated less than 200 million dollars for civil defense, practically putting all the burden on the states. Some of our states have been fair in the allocation of funds, but others just "passed the buck" to the cities. Local governments do not possess the tax resources to finance civil defense on an adequate scale. This applies to medical equipment and supplies as well as to other components of the civil defense structure.

Another important factor to be considered is the fact that in the field the wounds are almost entirely from bullets and explosive elements, such as shells and aerial bombs. Bad as these are, they are not so bad as the tremendous number of injuries that would result from an atomic blast, of hurled structural elements goring human bodies and crushing them beneath. Atomic radiation and burns would be major problems. Spending a half hour to see the Japanese medical color films of the Hiroshima tragedy is enough to give any civil defense director an idea of the magnitude of the problems to be faced.

All these factors were considered when we initiated the Toledo Medical Plan. We knew that we had only about 500 physicians and a correspondingly low number of other professional medical personnel. We had developed our basic civil defense plan, but the medical plan came as a later development.

Our academy of medicine, even before it was requested to do so, appointed an excellent committee on civil defense. Dr. Richard Hotz was made chairman, and among the members was Dr. Roscoe H. Snyder. Under the leadership of these two veterans of the gruelling Pacific campaign, our plan of organization and operations was initiated.

PRELIMINARY FACTORS IN PLANNING

Because of the extreme shortage of physicians, dentists, pharmacists, and nurses, it was imperative that the plan provide for the most efficient utilization of medical personnel possible. We could not afford to have doctors walking about among patients in casualty or collecting stations. The tragic picture of tens of thousands of casualties that may be thrust upon the city demanded that their care be on a mass production basis. The nature of casualties under atomic blasts demanded that all the seriously wounded who had a chance to survive be taken to points of definitive treatment as rapidly as possible. Triage, an inclusive medical term that I learned to understand and appreciate, was a professional function. This meant that, in the opinion of our medical committee, there must be physicians, dentists, nurses, and pharmacists right in the disaster area. This was a requirement the committee deemed not only practical but imperative.

We realize that medical personnel alone would be incapable of carrying out the tremendous task of evacuation. They would have to be supported by many times their number of trained and organized nonprofessional volunteers. Also, our city could not financially support a medical program, even on a matching fund basis, that would envision the expenditure of a million dollars or more. Another factor was that both personnel and equipment would have to be dispersed on as wide a scale as possible. Finally, the plan had to have city-wide acceptance, which could come only from city-wide participation.

THE GENERAL PLAN

The Toledo plan is in two phases. The first phase is the enlargement of our existing hospital staffs and facilities, as a mutual aid structure, to several times their normal bed capacities, to help in caring for the wounded of any other city in our area in case it was attacked and we escaped. This phase has been fully organized for some time. Phase 2 is the plan and organization to care for our own wounded if we were attacked. (Toledo is a critical target area. Also, it is in the orbit of Detroit, certainly one of the most desirable enemy targets in the United States. Incidentally, Ohio has more target cities than any other state.) It is in this phase that we cut a new road in the field of medical rescue organization.

Personnel.—We decided to organize medical field units, each to be composed of 1 physician, 1 dentist, 2 or more nurses, 2 nurses' aids, 1 pharmacist, and 80 trained laymen. We realized also not only the necessity of clergymen in the disaster area in administering spiritual aid to the injured but also the value of their moral leadership in the control of hysteria and panic and their need in comforting the distressed. So after a conference with our spiritual aid committee, we decided to attach two or more clergymen, one Protestant, one Catholic, and, insofar as available, one Jewish, to each team. The table of organization for the lay personnel is three deep, which is not only advisable but necessary to provide for around-the-clock operation. We could not do that with the professional persons, because there were not enough of them. So, under disaster conditions, our doctors, dentists, nurses, pharmacists, and clergymen would have to be in the field for many hours without even a hope of relief.

There was never any question about the cooperation of the medical profession, of doctors, dentists, nurses, and pharmacists. It was there, even in the beginning. Clergymen also responded to our call. So we had the professional persons for assignment to our medical field service, but we needed many thousands of lay volunteers. There we made a wise decision. This was to organize our medical field service around our school structure. We went before our council of parent-teacher associations and officials of our public and parochial schools and presented our program. Our primary request was that they provide 80 lay volunteers in the area of each school. Gordon Jeffrey, then PTA Council President; E. L. Bowsher, superintendent of public schools, and Monsignor Norbert M. Shumaker, superintendent of Catholic schools, said yes without hesitation. This was excellent. But we had another request.

Supplies.—We could not see any means of financing the medical supply program for our field operations. Again, our medical leaders had a practical idea. Why not ask the PTA or related organizations to provide triage supplies? So we did. We decided on a basic table of equipment of not less than 8 litters, 200 triangular bandages, 200 bandage pads, and 2 sets of splints for each unit. We did not even suggest that these be purchased. In fact, we asked that they be homemade, by persons from the PTA, mothers' clubs, Boy Scouts and Girl Scouts, and other organizations. This, also, was accepted. Next, we presented the project to a meeting of representatives of PTA, school principals, mothers' clubs, Boy Scouts, and Girl Scouts. Again, it was accepted. Through the schools, we distributed leaflets, with a brief explanation of the project, and asked parents and others to volunteer for the medical field service. Response was excellent. Unfortunately, we were not able to follow up as effectively as needed. While a number of teams were quickly organized and trained, in other cases organization was not effected. We realized, also, that a large staff of professional and lay leaders was essential.

At that time through mimeographed, illustrated circulars we explained how triangular bandages and bandage pads could be made from old bed sheets, to be sterilized in our hospitals and then packaged and stored in unit schools, and how a few 2 by 2's, with a piece of canvas or old rug, can be converted into a litter, and pieces of boards into splints. Soon Girl Scouts and others were collecting old sheets, and Boy Scouts helped PTA male members make litters and splints, while mothers' clubs and PTA members were making bandages. Our program is not completed; however, several months ago, the city council allocated funds for an assistant director and secretary for our medical section. Our volunteer staff is rather complete, in both the professional and the lay components. We are preparing for a really effective campaign this fall, to complete the entire organization before the end of the school year.

PLAN OF OPERATIONS

Our plan of operations is simple and practical. After the all-clear signal, our medical field units would assemble at their unit schools, and pick up their supplies. Large trucks, to be used as ambulances, would be furnished automatically by the motor transportation service. In addition to the organization equipment, lay members would bring with them blankets, a radio, and some other supplies.

We have 86 schools, and the maximum available medical field units would be about 90. Even if one-third of the teams were to become casualties, we would still have 60 units. Even a cursory examination brings out the dispersal value of this plan of organization. We are placing our medical resources in the city not in 1, 10 or 20, but in 90 baskets.

Upon radio direction and under zone control, the unit physician and professional personnel and a detachment of the lay volunteers would go into the disaster area. There, the function of the teams would essentially be that of triage, but they would be under professional direction. It would be the physician who would determine who should or should not be evacuated, and he would establish prioritites. Preparation of the seriously wounded for evacuation and their actual evacuation would be under his supervision. We would not send them to so-called collecting or casualty stations for sorting or triage. This would be done in the field, eliminating one very costly, in medical personnel, and time-consuming step in the process of getting the wounded to points of definitive treatment.

Of course, we are making the fullest possible use of first aid personnel, the men and women who have been and are being trained by the Red Cross, as a supplementary organization to the medical field service. In case of attack on Toledo, every drugstore would automatically become a first aid station, manned by first aiders. An atomic attack would produce thousands of light, or walking, casualties. Our medical field units would be too busy with the seriously injured to take care of them, so they would go to the nearest drugstore, where they would be treated within the limitations of first aid. Every drugstore has at least a limited amount of first aid supplies on hand. In addition, some 50 industrial plant dispensaries, organized under Dr. Charles F. Shook, of the Owens-Illinois Glass Company, would also become first aid stations. These dispensaries already carry a considerable amount of supplies in excess of their normal requirements. Heading the first aid service, under Dr. Snyder, is Victor L. Brenneman of the American Red Cross.

Of course, we realize that in an atomic attack on our city, nearly all our regular hospitals would probably be in the disaster area and could not be used. Accordingly, through the Lucas County Civil Defense Organization, we are establishing a system of 40 emergency or improvised hospitals, on the outside perimeter of the city. We have received or ordered medical supplies valued at approximately $38,000 on a matching fund basis. This amount is not impressive, but it would carry us through the first few hours of the disaster, until we could get more. Aside from the federal depot in Zanesville, Ohio is establishing a number of its own supply bases. One of these will be near Toledo. Within a few hours of the attack, we would be receiving medical supplies from our state depot. Toledo and Lucas County have separate civil defense organizations. To equalize responsibility for the medical services, James W. Ault, county civil defense director, has been delegated the responsibility for the organization of our emergency hospitals, with Dr. Henry A. Burstein as chief of the medical staff and Paul W. Kempe, superintendent of Riverside Hospital, as chief of administration.

TEST OF OPERATIONS

Last July 1 and 3 we conducted a large-scale demonstration called "Target: Toledo" simulating an atomic attack. Through voluntary contributions of materials and labor, we erected three full-sized frame houses in the football stadium of the University of Toledo, flanked by a simulated school house and drugstore, with a large army tent to represent an industrial dispensary. As the demonstration opened, the area represented a typical city neighborhood, with men and women going back and forth and children shooting marbles and playing ball and other games. As Warning Yellow was received, the staff went to the simulated control center. Using a public address system to simulate radio broadcast, Fire Chief Arnold F. Papenhagen explained the meaning of this advance warning. Then came Warning Red, with the wailing sound of the siren sending persons for cover. Soon the ominous drone of an Air Force bomber, coming a thousand miles for this purpose, could be heard. At 9:03 p. m. it was over the area, and an Army team exploded a planted bomb outside the stadium. Almost instantly, the roofs of the three houses ignited, with flames shooting toward the sky. The ghostly flames revealed a dramatic scene. Then there was no playing, no laughter, and but little movement. Scattered all about the area were casualties. In the drugstore, counters and cabinets were pushed aside, and a first aid station came into being. Already, wardens were assisting the lightly injured to the station, where first aiders were in action.

As the All Clear was sounded, radiological teams started monitoring the area, and, as it was declared safe, a fire engine manned by auxiliaries entered. Using water from two 3,000 gallon nylon tanks, it started to put out the fire. It was closely followed by rescue teams, which began the grim task of extricating persons from under debris. Then came the medical field teams, headed by their physicians. At this point, Dr. Hotz took over the narration, explaining each step in the triage procedure. Persons who had been made up for this purpose to represent different types of injuries were examined by the unit physicians, and triage was administered under their direction. They were evacuted on homemade litters to the school house, which now had become an emergency hospital. Powerful spotlights followed the procedure. The entire operation was orderly, notwithstanding that the several hundred participants had but one brief rehearsal. The demonstration closed with a brief address by Dr. Edward J. McCormick, president of the American Medical Association, emphasizing the importance of the medical phase of civil defense. Civil Defense officials came from all parts of the country to witness this demonstration, and each evening several thousand Toledoans were in the stadium. To us, it was a proof, as good as we could have without actual disaster operations, that our plans and organizational structure are practical and operationally sound.

COMMENT

I am enthusiastic about our medical plan and organization because I am convinced that under disaster conditions they would save the most human life possible within the limitations of our resources. Much study, deliberation, and painstaking care have gone into the preparation of the plans, in the outline of the procedure for each of the numerous personnel classifications, but the results are gratifying! We have an outstanding organization. It is being accomplished at a very small financial cost. We are doing it within our available resources, and with city-wide participation. I know that, if the tragedy of war should overtake us and we were attacked, our wounded would have the best medical care that we could provide. There would be no lost motion in the care of the injured, no haphazard methods in medical rescue operations. Every man and every woman in the service, from the medical director to the unit physician and litter-bearer on the field unit, would be a member of the team. They would function not as individuals but as units for maximum accomplishment.

The development of our plans and organization has been quite rapid, but every step has been taken with deliberate care, after intelligent reasoning. As a husband and father, it gives me great satisfaction to know that if I, or members of my family, or my relatives and friends and neighbors should suffer serious injuries, there would be physicians, dentists, nurses, and pharmacists to care for us, and even clergymen of our faith to comfort us; and, as the director of civil defense, I look into the future not only with a sense of realism but with the assurance that under disaster conditions we would save the maximum number of lives possible within the limitation of our resources. It is this which I, as director of civil defense, must expect from the medical profession. I could not expect more, and I could not accept less. Whatever we have accomplished or are accomplishing stems from the dynamic, intelligent, and conscientious volunteer leadership of professional and lay persons. Their cooperation has been of the highest type in both spirit and effectiveness.

Our objective has been and always will be the saving of human life, whether we are members of the medical profession or mere laymen. We do not need the oath of Hippocrates to accept this inviolable principle. It is a part of our heritage and of our training from the cradle to the grave. We are humanitarians, all. We also are a practical people. We know not only the moral and spiritual value but also the practical worth of human life. We know that as long as man lives and the earth gives up its treasures, he can create material things without limitation within our natural laws. But all the material things of the entire world could not create a single life!

We know, also, that, as long as the threat of atomic warfare shall hang over this foolish world, we must be ready, trained, and organized to care for the injured. In this, we have no alternative. It is our obligation and our responsibility. We must do all we can to save property, but the saving of human life comes first. This is the premise of the atomic age!

805 Adams St.

Penetrating Wounds of the Heart.—Penetrating wounds of the heart may produce either cardiac tamponade or, when the pericardium and pleura are severely enough lacerated, intrapleural hemorrhage. Most of the latter group do not survive long enough to permit institution of treatment. Those with cardiac tamponade restrict hemorrhage but may die of cardiac compression if the tamponade is not relieved. The diagnosis should be suspected in any one who has had a penetrating injury in the region of the pericardium. Shock, neck vein distention, muffled or absent heart sounds, diminished or absent cardiac pulsations, as seen on fluoroscopy, and enlarged cardiac silhouette by x-ray confirm the diagnosis. Immediate pericardial aspiration should be performed both for relief of tamponade and as further confirmation of the diagnosis. A retrosternal approach entering the skin just to the left of the xiphoid process is the method employed for this purpose. If there is an unsatisfactory response of the blood pressure following pericardial aspiration, blood should be administered intra-arterially to maintain satisfactory coronary circulation. Ice pick injuries may be sufficiently small that spontaneous closure will occur and in such cases no treatment other than the initial aspiration is indicated. However, these cases should be carefully observed and if further tamponade occurs, operative intervention is indicated. Injuries with slip knives, scissors, and larger instruments should be operated upon immediately. . . . The survival of patients [with heart wounds] has increased dramatically within the last ten years. The general use of blood replacement and antibiotics, the understanding of the physiology of acute cardiac tamponade, plus improved anesthesia, have all led to a lower mortality rate.—P. Jordan Jr., M.D., and G. E. Wilson Jr., M.D., Surgical Treatment of Vascular Trauma, *The Surgical Clinics of North America,* Aug, 1953.

HYPOKALEMIA DUE TO PERSISTENT VOMITING DURING PREGNANCY

Hyman S. Lans, M.D., Harvey A. Gollin, M.D., August F. Daro, M.D.
and
Ernest Nora Jr., M.D., Chicago

Vomiting occurs in approximately 50% of all pregnancies. Vomiting of pregnancy varies in degree of severity from the so-called morning sickness, or nausea, to the pernicious, or severe, type that may end fatally. Although the majority of cases of vomiting of pregnancy fall into the mild or self-limited group, there is a small percentage of cases in which constant and persistent vomiting develop and result in loss of weight, dehydration, and ketosis. There may be, in addition to the well-known syndrome of hyperemesis gravidarum, vomiting associated with other etiological factors.

During the past several years, the importance of potassium deficiency in many clinical conditions has been reported. Studies by Darrow,[1] Randall,[2] Butler,[3] and others [4] of the fluid and electrolyte losses in many clinical conditions have led to the understanding that losses of intracellular potassium frequently occur and that these losses lead to increased morbidity and mortality. It has been demonstrated [5] that losses of gastrointestinal secretions through vomiting or diarrhea result in loss of a large amount of potassium from the body and that these losses contribute significantly to the development of hypokalemia and potassium deficiency.

In the present report, we will describe eight cases of hypokalemia developing in pregnancies complicated by persistent vomiting. We will discuss the treatment of potassium deficiency in these cases.

METHODS

Patients admitted to the obstetric service of the Cook County Hospital because of pregnancy complicated by persistent vomiting were studied for abnormalities in serum potassium concentration. Laboratory studies routinely performed included serum sodium, chloride, potassium, and carbon dioxide comfining power and blood nonprotein nitrogen and creatinine. Blood was collected, except in emergencies, in the morning under fasting conditions. The daily fluid and electrolyte therapy were based on the laboratory determinations performed the same morning, and response to treatment was followed by daily blood chemistry studies on each patient. Sodium and potassium concentrations in serum were determined on a flame photometer, with lithium as an internal standard.[6]

CLINICAL MATERIAL

Clinical and laboratory data from the eight patients are summarized in table 1. Three cases histories are presented in detail. We consider that the normal range of serum potassium is from 4.0 to 5.6 mEq. per liter.[7] All patients in this report had a serum potassium concentration below 3.4 mEq. per liter, probably indicative of an intracellular potassium deficiency. All patients had little or no oral intake of food prior to admission. After admission to the hospital, hypokalemia occurred again after the parenteral administration of fluids without potassium, while oral feedings were withheld. Vomiting was pronounced and unremittent in all patients. Weight loss ranged from 4 to 25 lb. (1.8 to 11.3 kg.).

All the patients in this series exhibited lethargy, listlessness, apathy, and mental depression. Four patients were confused, and two were disoriented. Muscular weakness was present in all patients. Shallow respirations were evident in five patients. Two patients were jaundiced and laboratory studies indicated toxic hepatitis in both cases. In these cases, the cephalin flocculation was positive and the thymol turbidity was greater than 4 mg. per 100 cc.

Institution of therapy with potassium chloride given intravenously resulted in a striking improvement in mental attitude and muscular strength. In several cases, this appeared to be a lifesaving procedure. Although four patients were in critical condition on admission to the hospital, all responded to therapy and no deaths occurred. One patient (case 3), who had toxic hepatitis, had a premature labor at six months' gestation; a nonviable fetus resulted. All other patients continued their pregnancy to term without further complications.

Three patients had an elevated blood nonprotein nitrogen level. Urine output was scanty and highly concentrated in five patients. On institution of fluid and electrolyte therapy, the output of less concentrated urine increased, and the blood nonprotein nitrogen value returned to normal.

REPORT OF CASES

CASE 1.—A 32-year-old Negro woman, gravida 1, para 0, was admitted to the obstetric service of the Cook County Hospital on Oct. 7, 1950, because of vomiting of three weeks' duration. The patient had received prenatal care in another city. Her expected date of confinement was stated to be June 2, 1951. The patient had experienced nausea and anorexia since informed of her pregnancy four weeks before admission. During the three weeks prior to admission she had been able to retain only small amounts of liquids daily. The preceding week, she had had copious amounts of vomitus five to six times a day. There had been a 25 lb. (11.3 kg.) weight loss since the beginning of the vomiting. Physical examination on admission revealed an acutely ill, dehydrated woman

showing evidence of marked, recent weight loss. The temperature was 100 F rectally. The pulse rate was 90 and regular. The blood pressure was 132 systolic and 82 diastolic. The uterus was enlarged to the size of a six weeks' gestation.

Laboratory studies showed a hemoglobin level of 78% (12.1 gm., Evelrn colorimeter). Reaction to a Kahn test was negative. Urine contained 4+ acetone but no albumin or sugar. Microscopic examination gave normal results. Blood chemistry studies on admission disclosed a serum potassium of 3.4 mEq. per liter, with normal concentrations of serum sodium and chloride (table 2). The patient received fluids intravenously consisting of 2 liters of 0.9% sodium chloride solution and 2 liters of 5% dextrose solution on the day of admission and the following day. On Oct. 9, 1950, the patient was very lethargic, drowsy, apathetic, and at times completely disoriented. Electrocardiographic findings on that day were suggestive of hypokalemia, and the serum potassium level was found to be 2.9 mEq. per liter (table 2). We were called to see the patient at this time. Treatment with potassium chloride given intravenously was begun immediately. A gradual rise in the serum potassium was noted. The following morning apathy and lethargy had diminished. Administration of potassium intravenously was continued (table 2), and dramatic improvement on the second day of therapy coincided with an abrupt rise in serum potassium concentration. The patient continued to improve, and intravenous administration of fluids was discontinued on Oct. 13, 1950. The patient was discharged from the hospital to the prenatal clinic on Oct. 20, 1950, and continued her pregnancy to term without further complications.

Table 1.—*Clinical and Hematological Data in Eight Cases of Vomiting During Pregnancy*

8	23	6 weeks	10	3.4	130	85	70	34	1.0

* Normal range: potassium, 4.0-5.6 mEq. per liter; sodium, 138-148 mEq. per liter; chloride, 100-110 mEq. per liter; carbon dioxide combining power, 50-70 cc. per 100 cc.; nonprotein nitrogen, 20-40 mg. per 100 cc.; and creatinine, 1-2 mg. per 100 cc.

Case 2.—A 35-year-old Negro woman, gravida 2, para 1, was admitted to the hospital on Nov. 24, 1950, because of intractable vomiting of two weeks' duration. The patient had been having morning nausea and occasional vomiting since the fifth week of pregnancy. During the five weeks preceding admission, the vomiting had become more frequent, and, for the past two weeks, she had been unable to retain any solid food and only a slight amount of water daily. There was a 10 lb. (4.5 kg.) weight loss during the week and a half preceding admission. Physical examination on admission revealed an acutely ill, dehydrated patient with evidence of recent weight loss. Temperature and pulse were normal. The blood pressure was 130 systolic and 80 diastolic. The patient was very weak and showed no interest in her surroundings. Respirations were shallow and infrequent. The respiratory rate was 14 to 16 per minute. The uterus was the size of a four month gestation.

Laboratory studies showed hemoglobin level 79% (12.3 gm., Evelrn colorimeter) and leukocyte count 6,400 per cubic millimeter of which 87% were polymorphonuclear. Reaction to the Kahn test was negative. The urine contained no albumin or sugar, but the test for acetone was strongly positive. Microscopic examination gave normal results. Blood chemistry studies made on Nov. 28, 1950, showed a serum potassium concentration of 2.8 mEq. per liter (indicative of severe hypokalemia). Administration of potassium chloride intravenously in sodium chloride and dextrose solutions was started immediately. Twenty-four hours after initiation of this treatment, the serum potassium concentration was 3.3 mEq. per liter (table 3), and marked clinical improvement had occurred. On the following five days, potassium chloride was administered intravenously (table 3), and a gradual rise in serum potassium concentration resulted. On the sixth hospital day, the patient was able to retain oral feedings and intravenous administration of fluids was discontinued. The patient was discharged to the prenatal clinic on Dec. 13, 1950, and continued her pregnancy to term without further complications.

Case 3.—A 17-year-old white girl, gravida 1, was admitted to the obstetric service of the Cook County Hospital on Aug. 19, 1950, because of lower abdominal cramps and vaginal bleeding of five hours' duration. Menstruation had not occurred since February, 1950. Prenatal care had not been received. Vomiting had occurred four to five times a day during the past two months and had become intractable during the preceding five days with inability to retain any solid or liquid food. There was a 15 lb. (6.8 kg.) weight loss during the preceding five weeks. Physical examination on admission revealed a dehydrated, very ill, icteric patient with evidence of recent weight loss. Temperature and respirations were normal. The radial pulse rate was 90 per minute. Blood pressure was 135 systolic and 115 diastolic. The uterus was enlarged to the size of a six month gestation, and fetal heart tones were 130 per minute and regular. Rectal examination disclosed two-thirds effacement and 4 cm. dilatation of the cervix; the station was +2. Strong uterine contractions occurred every five minutes.

Laboratory studies showed hemoglobin level of 94% (14.6 gm., Evelrn colorimeter) and 13,600 leukocytes per cubic millimeter, 89% polymorphonuclear. Reaction to the Kahn test was negative. The urine contained 1+ albumin, 4+ acetone, 4+ urobilinogen, and no bilirubin. Microscopic examination gave normal results.

Administration of barbiturates for sedation and fluids intravenously consisting of sodium chloride and dextrose solutions was begun. The following morning, a baby boy weighing 3 lb. 6.5 oz. (1,550 gm.) was delivered. The girl's blood pressure six hours post partum was 120 systolic and 75 diastolic. The patient continued to vomit copious amounts of coffee-ground material. Blood chemistry studies at this time (table 4) disclosed a severe hypochloremia and azotemia. Liver function tests were indicative of toxic hepatitis. Sodium chloride and dextrose solutions were administered intravenously in amounts

* Administration of potassium chloride followed determination of the blood chemical data made earlier each day.

calculated to correct dehydration and replace gastrointestinal losses. In spite of this treatment, however, the patient rapidly became lethargic, very weak, and disoriented. Respirations were shallow. On Aug. 23, 1950, she was comatose. We were called to see the patient at this time. Further blood chemistry studies revealed a serum potassium concentration of 2.9 mEq. per liter (indicative of marked hypokalemia). Treatment with potassium chloride intravenously (table 4) was instituted immediately, and the patient received 8 gm. of potassium chloride during the next 10 hours. Within six hours after the administration of the first 8 gm. of potassium chloride, dramatic improvement occurred. The patient was alert, oriented, and able to sit up without aid. Treatment with potassium chloride intravenously was continued for the next two days (table 4). Continued clinical improvement was rapid as the serum potassium concentration returned to normal. On Aug. 26, 1950, the patient was able to take adequate oral feedings, and intravenous administration of fluids was discontinued. Jaundice subsided, and the patient was discharged to the postnatal clinic on Sept. 2, 1950.

COMMENT

Pathogenesis.—One of the major factors leading to development of potassium deficiency is the limitation of potassium intake. The average normal intake of potassium is from 3 to 4 gm., or 75 to 100 mEq., per day.[8] There is no storage of potassium in the normal adult; instead, the excess intake is excreted in the urine. In malnutrition or dehydration, cellular breakdown occurs with resultant release of potassium from the cell. This potassium is excreted in the urine. An inadequate intake of potassium, malnutrition, and dehydration were present in the majority of the patients in this study.

The kidney is the principal route of potassium excretion. The usual urinary excretion of potassium is 2 to 3 gm. per day. Although the daily total excretion of potassium may be decreased, renal losses continue even during periods of marked potassium deficiency. The renal mechanisms for potassium excretion are influenced by many extrarenal factors, including disturbances in acid-base balance, infusions of parenteral solutions, and body stress. All of these factors were present in the patients in this study. Prolonged parenteral use of fluids is often necessary in patients with vomiting to provide nutrition and prevent dehydration. The solutions used contain little or no potassium; therefore, patients sustained on these solutions alone receive an inadequate intake of potassium, and the resultant diuresis causes an increased renal loss of potassium.

In addition to the loss of potassium through increased renal excretion, the patients in this study had an additional source of potassium loss through vomiting. In previous studies,[9] potassium was found to be present in gastric juice in concentrations ranging from 6.5 to 27 mEq. per liter. Others [2] have reported concentrations of 40 mEq. per liter. Normally the potassium content of these secretions is reabsorbed; however, patients with a daily loss of 2 to 3 liters of gastrointestinal fluids may lose as much as 75 to 100 mEq. of potassium per day (equivalent to the potassium content of 5.5 to 8 gm. of potassium chloride). This loss of potassium contributes significantly to the development of potassium deficit.

Clinical Manifestations.—The commonest clinical picture encountered in potassium deficiency is a symptom complex consisting of gradually increasing weakness, loss of energy, anorexia, and mental depression.[10] Shallow, infrequent respirations are frequently noted, and death may result from respiratory paralysis. Abdominal distention, caused by paralytic ileus, is often observed.

Hypochloremia alkalosis that does not respond to hydration and sodium chloride therapy is indicative of potassium deficiency and readily responds to treatment with potassium chloride solutions administered intravenously.[9] Alterations in cardiac function are common in severe potassium deficiency. Cardiac arrhythmias, the development of systolic murmurs, and cardiac dilatation are observed clinically. The electrocardiographic changes with hypokalemia have received considerable attention.[10a]

TREATMENT OF POTASSIUM DEFICIENCY

The following routine is suggested as a basis for treatment of hypokalemia. Daily blood chemistry studies, including serum sodium, potassium, chloride, and carbon dioxide combining power, are necessary for accurate treatment of fluid and electrolyte abnormalities. Potassium may be added to all types of fluids given intravenously and subcutaneously. Concentrations should not exceed 3 gm. of potassium chloride per liter of fluid for parenteral use and should be administered at rates not exceeding 8 to 12 cc. per minute. More concentrated solutions or faster rates of administration may lead to high serum levels of potassium that are toxic to the heart and that result in heart block and cardiac arrest. We have not encountered this complication. Potassium may be administered in the above concentrations as long as adequate urine output is present (at least 800 cc. every 24 hours) and hypokalemia exists.

Three grams of potassium chloride are added to each liter of fluid for parenteral use so that the patient will receive 9 to 15 gm. of potassium chloride (121 to 202 mEq. of potassium) a day. This treatment is continued until the serum potassium level has been normal for 24 hours; after that 6 gm. of potassium chloride are administered daily. Parenteral administration of potassium is continued until oral feedings are tolerated. Since most foods are a good source of potassium, potassium salt therapy is no longer needed after the patient can be fed an adequate diet.

SUMMARY AND CONCLUSIONS

Eight patients with vomiting during pregnancy were found to have hypokalemia on admission to the hospital. The loss of potassium through vomiting, limitation of potassium intake, and increased renal excretion of potassium were the major pathogenic factors in the development of hypokalemia in these cases. The intravenous administration of potassium chloride solutions in the treatment of hypokalemia is discussed. Treatment of potassium deficiency is an important addition to the care of pregnant patients and is often essential for their survival.

AN OBSESSIVE-COMPULSIVE REACTION TREATED WITH PREFRONTAL PROCAINE INJECTION

J. Martin Myers Jr., M.D., Frank E. Nulsen, M.D., Harold Dillon, M.D., Calvin S. Drayer, M.D.
Manuel M. Pearson, M.D., Francis C. Grant, M.D.
and
Lauren H. Smith, M.D., Philadelphia

Injection of various substances into the frontal lobe of the brain has been one of the various methods utilized to treat intractable pain and certain psychiatric disorders since Moniz's original report on lobotomy in 1936.[1] He injected small amounts of alcohol in some of his early cases. Lindsay,[2] in 1950, described the injection of small amounts of procaine into the forebrain of three psychotic patients. Putnam [3] and Van Wagenen [4] have used procaine injections as a preliminary and temporary procedure in an effort to estimate in advance the possible effect of a surgical prefrontal lobotomy. Two of us (F. E. N. and F. C. G.)[5] have used multiple injections of much larger amounts of procaine for the relief of intractable pains from advanced carcinoma. This idea followed John Adams' [6] demonstration in San Francisco in 1950 that long-term changes in psychotic behavior resulted from massive frontal lobe procaine injections. More recently it has come to our attention that Bucaille,[7] in France, and Mandl,[8] in Germany, have also utilized such injections for pain since 1950.

In February, 1953, treatment utilizing Nulsen's procedure was initiated at the Pennsylvania Hospital Department for Mental and Nervous Diseases with certain selected psychiatric patients. These patients were those relatively inaccessible and lacking in response to psychotherapy. It was hoped that there would be increased accessibility and that psychotherapy could then be utilized so that the recovery process initiated by the temporary lobotomy could be enhanced and prolonged. Ten patients have been so treated. A severe obsessive-compulsive patient who was completely incapacitated showed a most abrupt and dramatic change that is reported here.

REPORT OF A CASE

A 52-year-old man was brought to the hospital by his wife on Feb. 24, 1953, because of a severe exacerbation of obsessive-compulsive reaction that had its first onset at age 19. For two months he had been obsessed with the fear that recipients of his bills would be harmed by some contamination he had gotten on them. For the month prior to admission he had made increasing demands on his wife for reassurance that he had not struck someone with his car or that he had not injured somebody by touching him. In the several days before hospitalization there was near delusional uncertainty. He became so indecisive and preoccupied that he was unable to dress or eat without physical aid and constant reassurance by his wife.

The patient was the youngest of seven siblings born into an upper middle class family. He did very well in school and was valedictorian of his high school class. He participated in such sports as baseball, tennis, and swimming. He entered a university when he was 18 years old but left in the middle of his sophomore year because after he had jumped over a tennis

net he felt he had injured himself inside. Subsequently, the patient had an appendectomy "for his nerves." At the age of 21 he developed obsessive thoughts about dirt and glass and was hospitalized in a private sanatorium for several months. From the age of 22 to 36 he worked in the family business but was too incapacitated most of the time to make any real contribution. He had few outside interests and stayed very close to his rigid, domineering, over-protective mother. His father died when the patient was 27.

After the family business failed (when he was 36) he stayed at home with his mother. At 40 years of age he met his future wife, who was herself convalescing from a "nervous breakdown." His mother died the following year, but his wife had already assumed the mother's protective and domineering role. From age 41 to 47 he worked in a war plant as an expeditor, but he lost his job in the first postwar lay-offs. Since then he has lived on the return from his investments.

In August, 1951, he was admitted to a psychiatric hospital because of his obsessive fears and showed improvement after receiving 10 electroshock treatments. He was readmitted there in June, 1952, after a relapse, and was again treated with electroshock with 14 convulsions. He was discharged moderately improved, continued in group psychotherapy, but relapsed within four months.

On admission to Pennsylvania Hospital, the physical and neurological examinations were within normal limits, except for evidence of weight loss. Blood and urine examinations were normal. Mental examination showed the patient to be extremely slow and indecisive in his movements. He would make many false starts before accomplishing simple acts. He had some peculiar mannerisms with his mouth and tongue. Speech and thought were very slow, and no spontaneous talk was offered. He seemed very tense. His mood was one of mild depression. He expressed concern over dirt and was careful to avoid touching objects touched by other patients. He was well oriented in all spheres, memory was intact, and retention good, but concentration was very poor. Simple calculations such as serial sevens were accomplished inaccurately and very slowly, with much indecision. Symbolization was good. Insight was absent. An electroencephalogram was reported as "low voltage fast frequencies and poorly developed rhythms dominated the tracing with an occasional scattered sharp wave being noted in both hemispheres."

The patient was treated with psychotherapy for the first month, but his condition became worse. He became more withdrawn and stayed in his room because of phobias, which took the form of delusional ideas of "getting something on" the male nurses that might harm them or impregnating one of the female nurses. He lost 13 lb. (5.9 kg.) during the month.

On March 24, 1953, bilateral frontal trephinations were done without incident or change in the patient. Two days later, with the patient under local anesthesia, a total of 45 cc. of 1% procaine was injected into the white matter of the frontal lobes. In 5 cc. amounts, 20 cc. was injected into the right frontal and 25 cc. into the left frontal lobe. The injections were made in the inferior medial quadrant of the usual plane for frontal lobotomy. During the injection the patient became, at one time, resistive, his pupils dilated and his speech was jerky; at another point he became pale and his respirations were shallow. At the conclusion of the injection the patient was confused. Within 24 hours the confusion had begun to clear markedly and the patient was found to be clinically more spontaneous in speech and activity. Within 48 hours marked changes were noted. He spoke freely and spontaneously of his plans for the summer, he participated in activities on the hospital grounds, ate and slept well, and showed very little evidence of hesitancy and indecision. When questioned he stated that he had fears, but he showed no concern about them. His score on a modified Malamid rating scale, which had hit a high of 52 just prior to injection, dropped abruptly to 10.

On April 8, 10 cc. of procaine was injected through the original trephine openings into each frontal lobe because his indecision had been noted to have increased slightly the day before. He withstood the procedure well and showed no marked autonomic reactions. Thereafter the improvement was maintained. He was much more expressive and active and even verbalized angry feelings directly. He moved about the hospital, and participated actively and spontaneously in group activities. He seemed friendly and relaxed. He gained 10 lb. (4.5 kg.) in weight. Serial sevens, which had taken 15 minutes to complete prior to treatment, were accomplished accurately in 20 seconds. Selected psychological tests that had taken seven and one-half hours before treatment required only 45 minutes. An electroencephalogram made 17 days after the second injection showed occasional slow and sharp waves throughout both hemispheres, with rhythms slightly better developed than in the electroencephalogram made before treatment.

The patient pressed for discharge stating that he felt well and that there was no need for his continued hospitalization. He denied that he had been ill, and dynamic psychotherapeutic efforts were not successful. He was discharged on April 24, 1953, as much improved, to be followed as an outpatient.

He returned to his home, where he has been active in gardening and some sports such as golf. He has again taken over the management of his affairs but has shown no inclination to obtain employment, which is not necessary for him. His wife has stated that he is better than at any time she has known him. Indeed, his lack of obsessiveness has been somewhat a matter of concern for her because of her own meticulousness. He has been socially more active and interested than he has been for some years. He has continued to gain weight. In the outpatient conferences it has not been possible to work with him on a dynamic unconscious level. He treats the therapist as somebody he is passively willing to come and report to about his garden, his trip through New England, and the like. He has continued free of incapacitation from his phobia for six months.

COMMENT

This patient showed a marked improvement of his severe obsessive-compulsive reaction after the injection of 45 cc. of 1% procaine into the white matter of the frontal lobes of his brain. With the injection were attendant autonomic nervous system reactions. Clinically, too, a marked confusion was produced, but the confusion started to clear within 24 hours. There were none of the other regressive signs found in many patients subjected to surgical lobotomy; he neither wet nor soiled. He needed no period of habit training. After the confusion had cleared he was free of psychotic symptoms and back to his usual personality functioning level. Although it had been hoped that dynamic insightful psychotherapy might be utilized, the continuation of his utilization of the mechanisms of denial made only supportive psychotherapy possible in the three months since his discharge from the hospital.

Of the other nine patients treated (all schizophrenics) the response to injection has varied from "recovered" to "no change." The complications from the treatment have been few; two patients had convulsions in the immediate post-treatment period but none thereafter, three had hyperpyrexia immediately post-treatment, and one soiled and wet for a week. Several patients have remarked that they preferred this type of procedure to electroshock. In all the confusion was brief and comparable to, or less than, that after brief electroconvulsive therapy.

SUMMARY

A severely incapacitated obsessive-compulsive patient was abruptly and dramatically improved by the injection of 45 cc. of 1% procaine into the white matter of the frontal lobes of the cerebrum through cranial trephines. A total of 10 patients so treated demonstrated that this procedure is safe, with few complications and with less resultant regressive phenomena than after surgical lobotomy

111 N. 49th St. (39) (Dr. Smith).

CLINICAL NOTES

INSTRUMENT FOR ENDOTRACHEAL ANESTHESIA DURING OROPHARYNGEAL SURGERY

Richard Thomas Barton, M.D., Beverly Hills, Calif.

It has always been important to maintain an adequate airway during any general anesthetic, especially for any type of oral surgery performed under general anesthesia. With the increasing use of intravenous administration of anesthetics, it is even more vital. Attempts have been made in the past to perform operations such as tonsillectomy on adults by using endotracheal intubation, but the surgeon usually found that the tube obstructed the operating field or tended to slip out of the glottis. It is the purpose of this report to describe a new endotracheal tongue blade,* which is adaptable to either the Crowe-Davis or the McIvor mouth gag and which affords greater safety and better exposure.

DESCRIPTION

The stainless steel tongue blade is pictured in figure 1 and is constructed in three sizes to pass a no. 24 French, 28 French, and a 38 French endotracheal tube. These can be used for a small child up to an adult. The carrier tube is built into the tongue depressor in such a way that the lingual half pushes into the soft tissue of the tongue and only the oral half protrudes into the mouth. In this way there is a minimum of obstruction of the operating field.

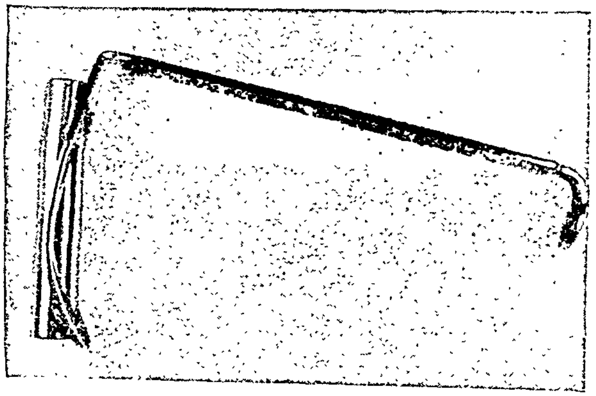

Fig. 1.—Profile of endotracheal tongue blade with carrier tube inserted in tongue depressor.

The technique used is outlined briefly. The patient is anesthetized with whatever agent desired (cyclopropane, thiopental [Pentothal] sodium rectally or intravenously, or succinylcholine [Anectine] chloride) and an endotracheal tube inserted. Thereafter, the mouth gag, (either Crowe-Davis or McIvor) with the proper-sized blade attached, is placed in the mouth while the endotracheal tube is threaded through the tongue blade as seen in figure 2. When the gag is opened, an excellent exposure is achieved with the endotracheal tube held away from the operative field and not likely to slip out of the glottis. With the blade and endotracheal tube in place, the McIvor gag rests on a Mayo stand, which holds the surgical instruments directly in front of the surgeon. The patient should be in the Rose position with the surgeon sitting at the head.

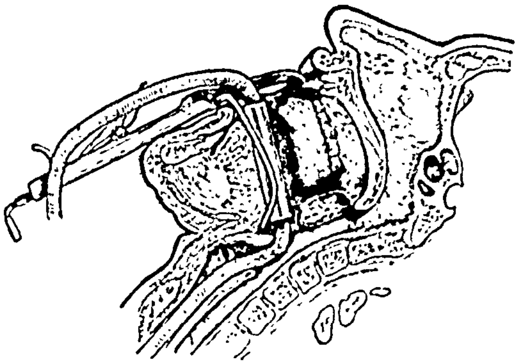

Fig. 2.—The mouth gag with the endotracheal tongue blade is introduced into the mouth while it is threaded over the endotracheal tube. Thereafter, the handle of the gag is elevated so as to elevate the posterior one-third of the tongue and the epiglottis.

After the operation is completed, the tracheobronchial tree is suctioned with the catheter, and the patient is awakened by removal of the endotracheal tube. These conditions represent the anesthesiologist's "ideal."

COMMENT

The technique described by Johnson [1] has the advantage of permitting a painless operation with a pleasant induction of general anesthesia. It has not been widely accepted, however, because the endotracheal tube is not used. It is generally agreed that the Johnson technique is a dangerous one without intubation, because of possible aspiration, anoxia, and hypoxia.[2] Anesthesia is safely maintained only by an endotracheal tube. This instrument provides a satisfactory solution to the problem.

SUMMARY

The endotracheal tongue blade described has been used routinely in children and adults during the past six months. The results have been uniformly satisfactory. The advantages of the instrument described over other techniques are: (1) complete protection against laryngospasm, (2) complete protection against tracheobronchial aspiration, (3) complete protection against hypoxia, (4) pleasanter induction for general anesthesia, (5) quicker recovery of consciousness after general anesthesia, and (6) an unobstructed surgical field for all types of oropharyngeal surgery.

EVALUATION OF PSEUDOALBUMINURIA FOLLOWING CHOLECYSTOGRAPHY IN SEVENTY-SIX CASES

J. E. Holoubek, M.D.
W. H. Carroll, M.D.
G. M. Riley, M.D.
and
R. B. Langford, M.D., Shreveport, La.

Since 1942 iodoalphionic acid (Priodax) has been available in the United States for cholecystography. This iodine-containing preparation with the chemical name beta-(4-hydroxy-3,5-diiodophenyl)-alpha-phenylpropionic acid, is similar to the German drug Biliselectan synthesized by Dorhn and Diedrich in 1940.[1] Iodoalphionic acid contains 51.38% iodine and is usually taken orally in a dose of 3 gm. It is contraindicated in cases of acute nephritis and uremia and in acute disorders of the gastrointestinal tract.

During the past year a new cholecystographic medium called iodopanoic acid (Telepaque) [2] has been under investigation. It has proved to be of low toxicity, is effective in small doses, produces satisfactory visualization of the gallbladder, and often demonstrates the common bile duct. This preparation contains 66.68% iodine and is a brand of beta-(3-amino-2,4,6-triiodophenyl)-alpha-ethylpropionic acid. It is generally agreed that both iodoalphionic acid and iodopanoic acid are better tolerated and have definite advantages over tetraiodophenolphthalein.

Unlike tetraiodophenolphthalein, which is excreted by the colon, iodoalphionic acid and iodopanoic acid are mainly eliminated by the kidneys. Modell [3] has reported a transient albuminuria, lasting from one to seven days, in a majority of cats given large single oral doses of iodoalphionic acid. Howard [4] demonstrated that the preparation had no injurious effect on the pancreas. Both iodoalphionic acid and iodopanoic acid produce no evidence of renal or liver damage in experimental animals when used in the small amounts necessary for cholecystography. Seedorf [5] and co-workers have reported that a false positive reaction for albumin will occur in the analysis of the urine of a significant number of patients receiving the standard dose of 3 gm. of iodoalphionic acid.

In this study 76 patients were subjected to visualizations of the gallbladder with the use of a radiopaque dye, either iodoalphionic acid or iodopanoic acid. A urinalysis was made before and after cholecystography. Of the total number of tests, 40, or 52.6%, were negative for albumin on the day of cholecystography. Roberts' reagent (5 parts saturated solution of magnesium sulfate plus one part nitric acid) was used in all of these tests. There were 36 positive reactions, varying from a trace to 4 +. Fifteen patients had a 4 + reaction, 5 had a 2 + reaction and 16 showed a trace. In a recheck three days later reactions to all of these tests were negative. There was no significant difference whether iodoalphionic acid or iodopanoic acid was used in the production of the positive reaction for albumin using Roberts' reagent. Follow-up examinations in these cases failed to reveal any evidence of kidney disease.

SUMMARY AND CONCLUSIONS

The fact that it is the actual presence of iodoalphionic acid (Priodax) in the urine that causes pseudoalbuminuria has been proved by laboratory tests. Use of the heat and acid test for albumin detection in the urine will avoid this false positive reaction. Laboratories using Exton's reagent (sodium sulfate plus sulfasalicylic acid), the Heller ring test (nitric acid), or Roberts' reagent (5 parts saturated solution of magnesium sulfate plus one part nitric acid) for albuminuria detection should routinely check all positive reactions with the heat and acid test. Detectable amounts of iodoalphionic acid and iodopanoic acid (Telepaque) are present in the urine not only the morning after the ingestion of the drug but the following day and occasionally even on the third day. It is concluded that albuminuria occurring after administration of the usual dosage of iodoalphionic acid or iodopanoic acid does not indicate renal irritation due to the drug and should not be considered to be due to kidney disease.

ACUTE ULCERATIVE COLITIS SUCCESSFULLY TREATED WITH CHLORAMPHENICOL

REPORT OF CASE DUE TO SALMONELLA PULLORUM

John P. Doenges, M.D., Olney, Ill.

The two Salmonella, gallinarum and its variant pullorum, responsible for white diarrhea of chickens, until recently have been considered nonpathogenic for man. An acute gastroenteritis, violent in onset and course, but usually self-limiting in a period of 48 to 72 hours, has been attributed to the S. pullorum.[1] From the first report of this pathogen in 1941, by Edwards and Bruner,[2] until 1950, S. pullorum had been isolated from human patients 39 times.[3] In the case reported, the infection did not follow the usual self-limiting course, and special therapeutic measures were necessary to arrest the course of the disease.

REPORT OF A CASE

This patient was a 42-year-old white woman who was admitted to the Olney Sanitarium with the chief complaint of persistent, bloody diarrhea. Her illness had first started about five weeks prior to admission, with a severe shaking chill followed by a rise of temperature to 102 F. Other symptoms, including nausea, vomiting, cramping, abdominal pain, and marked generalized weakness, appeared in rapid succession. She was seen by her family physician and treated with aureomycin without any appreciable benefit. A barium enema, approximately one week after the onset of symptoms, showed a picture characteristic of an acute colitis. Other therapeutic measures were tried without success; in fact, the diarrhea became more pronounced, with 8 to 10 watery, spurting movements per day. During the last week prior to hospitalization, the stools became frankly bloody and she had daily elevations of temperature up to 102 F.

On reviewing the history with the patient, it was found that prior to her illness there had been an epidemic of sickness in her flock of chickens. They had seemed droopy, and several of them had diarrhea. She was quite proud of the fact that she had nursed several of the sickest chickens back to health. The fact that no one else became ill would indicate that the transmission was by direct contact rather than from ingestion of infected eggs.

The findings on routine physical examination were limited entirely to those of the abdomen and gastrointestinal tract, except for the evident weight loss and generalized marasmus. The abdomen was distended, and there was slight generalized tenderness, but no organs or masses were palpable. Anoscopic examination showed numerous pinpoint ulcerations, with active bleeding from many of these areas.

The laboratory examinations were as follows: erythrocytes, 5,050,000; hemoglobin, 109%; and leukocytes, 16,950, with 87% polymorphonuclear cells, 12% lymphocytes, and 1% eosinophils. The urinalysis was normal. Cultures of the stool showed S. pullorum as the predominating organism. There was agglutination with pullorum antigen K and the patient's serum. Antibiotic sensitivity tests showed small inhibitory zones around the disks of highest concentration of chloramphenicol (Chloromycetin) and streptomycin. Blood cultures and urine cultures were negative repeatedly.

This patient had a long period of hospitalization, which was made necessary by the resistant diarrhea and fever. During the first week, she was treated with succinylsulfathiozole (Sulfasuxidine) and chlortetracycline (aureomycin), with no change in the character or frequency of stools. There were daily spikes of temperature to 103.5 F to 104 F, with a rapid pulse and marked systemic toxicity. During the second week, she was started on chloramphenicol, 1 gm. every 24 hours; and, during this period the temperature spikes were less high and the stools diminished from 8 to 10 per day to 3 to 4 per day, but there was still gross blood present in almost every stool. The dose of chloramphenicol was then increased to 2 gm. per day, and from then until her discharge there was gradual improvement in all symptoms; however, a stool on the 20th day of hospitalization still grew out a S. pullorum on culture. A stool culture one week later failed to grow this organism.

The patient's recovery was uneventful, and there was no recurrence of symptoms. Stool cultures and serum agglutination tests one month after discharge were negative for S. pullorum.

COMMENT

S. pullorum has been reported as the etiological agent in individual cases and epidemics of an acute dysentery. In each instance, where it was possible to trace the route of transmission, infected raw or improperly cooked eggs played a role.[4] In the case presented here, transmission in all probability came from direct contact with the infected bird. This patient's flock was studied after the nature of her disease was determined, and 3 of 139 birds gave a positive agglutination for S. pullorum. Twenty-four birds had previously been culled from the flock because of diarrhea.

This case was unusual primarily because of the severity of the infection. In all previously reported cases the infection was self-limiting after three or four days, whereas this patient's disease progressed to an ulcerative phase. Sensitivity tests showed that this organism was resistant to penicillin, aureomycin, and the sulfa drugs and only sensitive to the highest concentrations of chloramphenicol and streptomycin. Prolonged therapy with chloramphenicol eventually brought about clinical and bacteriological remission.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT TO THE COUNCIL

The Council has authorized publication of the following report.

R. T. STORMONT, M.D., *Secretary.*

CHANGES IN THE CONSISTENCIES OF COMMERCIAL CONTRACEPTIVES

Clarence J. Gamble, M.D., Milton, Mass.

MEASUREMENT OF CONSISTENCY

Mechanical obstruction to the progress of sperms, provided by contraceptive jellies and creams, is believed to be an important element in the protection from pregnancy that they provide. To give efficient obstruction, clinicians believe that the material should be sufficiently fluid to spread throughout the vagina and establish a barrier over the os uteri. It should not, however, be so liquid as to leak out of the cavity or to be too readily displaced from the os by coital or postcoital movements.

For comparisons between the consistencies of contraceptive materials, measurements have been made of their viscosities by determining the rate at which a known pressure will force them through a tube.[1] Because of their semisolid nature the results found are not constant with different diameters and pressures as they would be with liquids. The order of apparent viscosities of various materials in which these are nearly equal, therefore, may change somewhat as diameters or pressures are changed. In consequence, such measurements of semisolid materials are to a certain extent arbitrary. In the absence of more perfect indices of consistency, however, the apparent viscosity seems to be a useful one.

For the measurement of consistencies of heavy oils, use has been made of an instrument known as a *mobilometer*. The dimensions have been adapted by Shedlovsky[2] for convenient use with contraceptive materials (see figure). The jelly or cream is placed in a cylinder and brought to body temperature. The time is then determined that is required for a perforated disk to be pushed a standard distance through the material by the force of a known weight. While the instrument does not

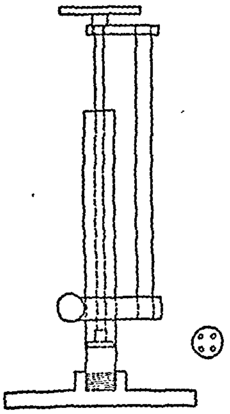
2. Shedlovsky, L.; Belcher, D.; Levenstein, I., and Bodner, H.: Changes on Aging in Consistency of Some Commercial Contraceptive Jellies, Human Fertil. 8:97 (Dec.) 1943.

determine true viscosities, it provides a convenient though somewhat arbitrary method of determining relative consistencies.

In Shedlovsky's instrument, which has been used for the measurements given, the inside diameter of the cylinder is ½ in. (1.27 cm.). The disk, mounted on a rod ⅛ in. (0.32 cm.) in diameter, is 0.485 in. (1.23 cm.) in diameter and $\frac{3}{32}$ in. (0.24 cm.) thick. It is perforated by 4 holes, each $\frac{1}{16}$ in. (0.16 cm.) in diameter. The pan at the top of the rod was loaded to give a total weight including disk and rod of 50 gm.[3] After more than 10 minutes is allowed in a waterbath at 37 C for temperature equilibrium, the time was determined that was required for the disk to fall 10 cm. through the contraceptive material from its upper surface.



Mobilometer designed by Shedlovsky, Belcher, Levenstein, and Bodner[2] for measuring consistencies of contraceptive material.

Stirring of a jelly, such as that involved in the passage through it of the mobilometer disk, usually resulted in a lower mobilometer time. For this reason only one determination was made with each filling of the instrument. The extrusion of the jelly from the tube in which it was dispensed probably lowered its mobilometer time, but this manipulation was the same as that required for its clinical use.

DESIRABLE CONSISTENCIES

No correlation has been established between the apparent viscosity as measured by the mobilometer and the effectiveness of a jelly or cream in preventing pregnancy. The difficulties of arranging such a test, the impossibility of securing materials that are equal in spermicidal activity yet differ in consistency, and above all the high cost of each failure of protection give little hope that a satisfactory test of this correlation will be arranged in the foreseeable future.

For the present we are forced to rely upon the opinions of clinicians based on a priori reasoning. For an approximate indication of these opinions, samples of contraceptive jellies and creams of known mobilometer times were submitted at 37 C to a group of 12 clinicians who had had extensive experience in the contraceptive field. They agreed that those with times of 20 seconds or less were too watery, and those with times of 5,000 seconds or more were too thick. Such a definition of the limits of desirable consistency is not completely satisfactory but appears to be the best available.[4]

CONSISTENCIES OF COMMERCIAL CONTRACEPTIVES

Shedlovsky showed that some manufacturers distribute contraceptive materials of unsatisfactory consistencies according to the definition given.[2] Of 46 brands tested in 1942, 15, or 33%, were too thick or too thin. This was also true of 25% of 51 brands which I tested in 1943, and of 14% of 22 brands secured in 1949.

To learn the recent trend, 60 brands made in the United States in 1951 were tested within a month of receipt from the manufacturer, dealer, or clinic. Eleven, or 18%, had mobilometer times of 20 seconds or less or 5,000 or more, and were therefore of unsatisfactory consistency according to the opinions of the clinicians quoted. It is hoped that the manufacturers will make this proportion smaller in the future.

The median time for the 60 brands was 116 seconds. The times of 25% of the brands were 42 seconds or less, and of the highest 25%, 235 seconds or more.

CHANGES OF CONSISTENCY WITH AGE

Early in the study of contraceptive jellies and creams, it was found that some gradually liquefied; others became unduly solid, and still others separated into liquid and solid portions. Each of these changes made them clinically unsatisfactory. For the protection of the consumer, such changes should not occur within the period elapsing between manufacture and final use.

A study of such changes was made by Brown,[5] who examined samples of 57 brands secured in 1941. He found that after 11 months at 37 C, 20 of these, or 35%, were unsatisfactory; they were either too fluid or too solid or had separated into solid and liquid portions. After 14 months at the same temperature, the number had increased to 40, or 70%. Stored at the refrigerator temperature of 8 C, 79% had good consistencies after 14 months, but such care is not to be expected in the usual pharmaceutical distribution.

Shedlovsky,[2] using his mobilometer, made a similar study of 17 brands secured in 1941 that had initial times of 24 to 750 seconds. After 12 months at room temperature, 5 of these had times of 20 seconds or less. After 4 months at 38 C, 10 (59%) were in this unsatisfactory group.

To secure information on the durability of subsequently manufactured commercial contraceptive materials, samples were tested after varying periods of storage. As in the reports of Brown[5] and Shedlovsky,[2] some of the tubes were kept at room temperatures (about 25 C) and some at 37 C. The latter temperature may be encountered on the shelves of druggists in the warmer parts of the country. Since most chemical reactions proceed more rapidly at higher temperatures, it is believed that if keeping qualities are satisfactory at 37 C, a factor of safety is indicated for the material in question under the more usual storage conditions.

Of the 51 brands secured in 1943, the proportion of 25% found unsatisfactory on receipt had increased after 12 months at room temperature to 37%, and after 24 months to 51%. Changes were more rapid at 37 C; the proportion found unsatisfactory after one and two years was 51 and 59% respectively.

More frequent determinations were made of 27 brands believed to be among those most widely distributed. Groups of 12 tubes from the same batches were secured in 1945, 1948, and 1949. The mobilometer times of 8% of these were outside the range of 20 to 5,000 seconds when received. This proportion had increased after one, two, and three years at room temperatures (average, 25 C) to 12, 18, and 30% respectively. Of the 1945 and 1948 samples, 42% were unsatisfactory after four years; of the 1943 samples, 61% were unsatisfactory after five years.

Changes were more rapid in samples kept at 37 C, some of the samples lasting less than a month. After two months, 30% were outside the satisfactory range. After one, two, and three years, the proportions were 58, 65, and 78% respectively. In the two earlier years, 82% were unsatisfactory after four years; of the 1943 samples, 83% were too thick or too thin or had separated after five years. These results show that satisfactory consistencies of contraceptive materials are possible after five years at room temperature and at 37 C. They also indicate that some materials become too thick or too thin after one or two years at room temperature and after one or more months at 37 C.

ACCELERATED AGING TESTS

Almost all of the materials were found to retain satisfactory consistencies longer at room temperatures than they did at 37 C. Most of those that became unsatisfactory at room temperature during the period of study were among the less durable at 37 C.

---

[3] Shedlovsky[2] used a total weight of 46.5 gm. For standard measurements it seemed preferable to use the rounded weight of 50 gm., which was employed in the times herein reported.

[4] To assist the reader in understanding these values, mobilometer times were determined for some familiar liquids and semisolids. These were measured at room temperature (24 C), the condition under which the reader probably has seen them. The times in seconds were: automobile lubricating oil, S.A.E. 30 (average), 1.5; S.A.E. 60 (heavy, motorcycle oil), 10; honey, 20 to 1,820; molasses, 20 to 70; Karo corn syrup, 30; Knox dessert gelatin prepared according to directions and allowed to set in the mobilometer tube, 900; set in a cup and transferred to the mobilometer, 300; a second determination after the gelatin had passed twice through the holes in the disk of the mobilometer, 60.

[5] Brown, R. L.: Changes of Consistency of Contraceptive Preparations During Storage, Human Fertil. 7: 161 (Dec.) 1942.

[6] The median period of satisfactory consistency was about one month at 50 C (1945 and 1948) and five months at 45 C (1949). The correlation coefficient between the rank of durability at 37 C and that at the higher temperature was 0.2 in the 1945 group, 0.9 in 1948, and 0.6 in 1949.

To determine whether the rates of change in storage at 45 or 50 C would provide an index of the durability at the lower room temperatures, some of each group of 12 tubes were examined after keeping them at one of these higher temperatures. Again the durability was found to be less at the higher temperatures. Although such an abbreviation of the test period by the greater temperatures may be of value to the manufacturers in searching for durable mixtures, the correlation was not found sufficient to indicate that the results are useful to clinicians.[6]

CORRELATION BETWEEN MOBILOMETER TIMES AND PENETROMETER MEASUREMENTS

The Braun penetrometer has been used by some manufacturers to control the consistency of their contraceptive materials. This determines the distance to which a conical dart of standard design and standard weight penetrates into a semisolid material after falling a standard distance.

To determine the extent of correlation between the penetrometer and mobilometer measurements, samples of 22 brands secured in 1949 were tested by both methods. To avoid a possible effect of the stirring involved in extrusion from the container in which the material was packed, the sealed end of the tube was opened with as little disturbance of the jelly or cream as possible. After prolonged immersion in a waterbath at 37 C, the penetrometer dart was allowed to fall into the material, and the distance of penetration was determined.

The correlation between mobilometer and penetrometer measurements was negative as would be expected; in most instances a higher mobilometer time was associated with a lower penetration of the falling dart. The correlation however was slight; the correlation coefficient was -0.11.

This low correlation suggests that the two instruments measure different qualities. The most obvious difference is that the penetrometer causes a distortion of shape that is very rapid compared with that observed in the mobilometer. No evidence is available to show that the measurements of either instrument are superior to those of the other as a measure of clinically desirable qualities.

COMPOSITION OF CONTRACEPTIVE MATERIALS

It is important for progress in the contraceptive as in other medical fields that physicians should prescribe only mixtures whose compositions are known to them. If secret mixtures of the patent medicine type are used, there can be no assurance that materials ordered in the future will be the same as those found successful today. Furthermore, it will not be possible for the prescriber to improve future mixtures by choosing components that are successful and by avoiding those that prove unsatisfactory.

The Food and Drug Administration has recognized the importance of knowing the composition of contraceptive mixtures by requiring that the active ingredients be printed on the package. For contraceptive effectiveness the barrier action of the jelly-forming or cream-forming ingredients is of such importance that they are active ingredients and should be listed, along with those ingredients added for their spermicidal action.

SECRET MIXTURES

Of the 62 brands whose spermicidal times were tested in 1949,[7] 38% were secret mixtures. For 70 brands of 1951,[8] the proportion was 26%. That manufacturers may consider the unrevealed ingredients more profitable to sales is suggested by the fact that the maker of a widely advertised new material states that its formula is secret.

SUMMARY

A mobilometer provides a convenient measurement of the consistency of a contraceptive jelly or cream related to its viscosity. A group of experienced clinicians considered contraceptive jellies and creams unsatisfactory whose times by Shedlovsky's mobilometer were 20 seconds or less, or 5,000 seconds (83 minutes) or more. For 60 brands of contraceptive materials secured in 1951, the median time found was 116 seconds. Eleven of the 60 brands, or 18%, were found to have an unsatisfactory consistency on receipt. Of samples of the more widely distributed brands secured in 1945, 1948, and 1949, 18% were found to have an unsatisfactory consistency after two years at room temperature. Stored in an incubator maintained at 37 C, 58% were unsatisfactory after a year, and 62% after two years. Mobilometer times of the contraceptive materials tested were found to have no significant correlation with penetrometer measurements. Of the 70 brands secured in 1951, the formula could not be obtained from the manufacturer for 26%. Physicians using these materials of secret composition can have no assurance that future prescriptions will give the patient the same degree of protection. In contraceptive mixtures, the jelly-forming or cream-forming materials are considered active ingredients.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

APPARATUS ACCEPTED

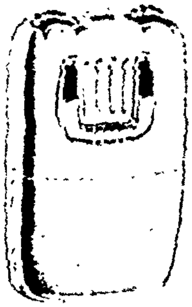
The following additional products have been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

RALPH E. DE FOREST, M.D., *Secretary.*

Fortiphone Hearing Aid, Model 20 A

Fortiphone Ltd., Fortiphone House, 247 Regent St., London, England, 1, W. Distributor: Anton Heilman, 75 Madison Ave., New York 16.

The Fortiphone Hearing Aid, Model 20 A, uses three English-made vacuum tubes for amplification and is powered by a 1.5 volt Vidor A-battery and a 22.5 volt Siemax B-battery. It is capable of giving a higher acoustic gain than is the Fortiphone Hearing Aid, Model 21 C, but also has an automatic volume control, referred to as the AVC, which limits the maximum output of the instrument and prevents the intensity of sound from reaching the user's threshold of pain.



Fortiphone Hearing Aid, Model 20 A

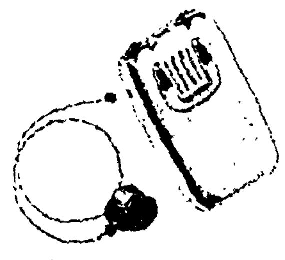
The body of the instrument measures 98 by 60 by 23 mm. and weighs 117.7 gm. The added weight of batteries, earphone, and earphone cord make a total of 180.5 gm.

The Council obtained evidence that this device was soundly constructed and performed as claimed by the manufacturer.

Fortiphone Hearing Aid, Model 21 C

Fortiphone Ltd., Fortiphone House, 247 Regent St., London, England, 1, W. Distributor: Anton Heilman, 75 Madison Ave., New York 16.

The Fortiphone Hearing Aid, Model 21 C, uses three English-made vacuum tubes for amplification and is powered by a 1.5 volt Vidor A-battery and a 22.5 volt Siemax B-battery. The body of the instrument measures 98 by 60 by 23 mm. and weighs 119 gm. With batteries, earphone, and earphone cord the total weight is 175 gm. Earphones are supplied for air and bone conduction.



Fortiphone Hearing Aid Model 21 C

Evidence of satisfactory construction and performance was obtained by the Council.

QUESTIONNAIRE ON POSTGRADUATE EDUCATION

Postgraduate education for practicing physicians has become increasingly popular since the end of World War II. The Council on Medical Education and Hospitals has received since the war a large volume of correspondence requesting advice and information from both the producers and the consumers of postgraduate medical education. During these years it has been impossible for the Council to do more than answer superficially these numerous inquiries. The House of Delegates, therefore, authorized the Council to make a thorough study of this problem, and in April, 1952, a member was added to the staff to make such a study. The first steps were to analyze all data that were already available in the files of the Council and then to visit all the medical schools in the United States, many of the state medical societies, the state health departments, hospitals, clinics, special societies, voluntary health agencies, and a variety of other organizations engaged in postgraduate medical education. It became apparent that the material thus obtained gave only a part of the picture and that the physicians themselves who desire to undertake postgraduate courses should be canvassed for their views on the matter. Accordingly, a survey is now being made of about 18,000 doctors, utilizing for this purpose a questionnaire that was mailed from this office November 10. The questionnaire was sent to physicians in all parts of the country, and it is requested that they be filled out and returned to the Council office in A. M. A. headquarters not later than November 30.

It is expected that a comprehensive view of the whole field will result from this more balanced approach to the problem. The study is also expected to suggest recommendations for the future activities of the Council in this field. All information from the questionnaire will be treated anonymously, and no coding device will be used to identify those who answer. The cooperation of physicians in answering promptly and accurately the various questions will be greatly appreciated. The ultimate benefit should be an extension and improvement of the ways and means that physicians have found most effective in keeping up-to-date with the progress of medicine.

MILITARY REQUIREMENTS FOR PHYSICIANS

The requirements of the Department of Defense for medical officers are of interest to all those physicians who are obligated for military service. Those obligated are also interested in the approximate time they may be required to enter the military service. In view of this, the estimated requirements of the Department of Defense for physicians for the next two years are here presented.

Future requirements for physicians are directly affected by and based on the total requirements for military personnel. The estimates of future military needs for personnel are based on an assumption of the type and extent of future military operations. For the purpose of this presentation, it is assumed that the international situation with respect to employment of the armed forces of the United States will remain unchanged. Any increase or decrease of military activity as a result of the international situation will alter the military needs for physicians.

At the inception of the Korean emergency on June 25, 1950, the military physician strength of the armed forces was composed of several categories of medical officers. These were regular medical officers, including those in residency training, and reserve medical officers, including career reservists, interns, and reservists who entered military service for a short tour of duty as a result of the "moral suasion" program. Immediately after the Korean emergency, medical reserve officers were involuntarily ordered to duty to keep pace with the increase in total military personnel and operational activity. With the enactment of the "Doctor-Draft" act (Public Law 779, 81st Congress) on Sept. 9, 1950, civilian physicians became liable for military service for a maximum of 21 months, which later was extended to 24 months' service.

The total military physician strength of almost 6,200 in June, 1950, increased to approximately 13,500 in June, 1951, and has been maintained near that strength to date. As reservists were released from duty on completion of their required tour, other physicians entered the military service as replacements. To build up and maintain the required number of military physicians, a total of 17,205 physicians entered the military service during fiscal years 1951, 1952, and 1953. There is a cyclic nature to the needs of the armed forces for physicians, the greater requirements occurring in the odd-numbered fiscal years and the smaller requirements occurring in the even-numbered fiscal years. This cyclic change in yearly increments is primarily the result of the specified length of service required of medical officers brought to duty under the impetus of the "Doctor-Draft" act. Thus, the number of physicians entering active duty in the armed forces in 1951 was 7,835; in 1952 it was 3,014; in 1953 it will be 6,356; and, in 1954 and 1955, it probably will be 3,100 and 5,300 respectively.

It is understood that the total medical officer strength in the armed forces will decrease during the next 12 months to a total strength of approximately 11,500 and will remain at that level barring changes in the military situation. To fill this requirement, it is estimated that a total of 8,400 physicians will enter the military service during fiscal years 1954 and 1955.

During the first quarter of fiscal year 1954 (July through September, 1953) approximately 1,950 physicians entered the military service. These physicians comprise those who were commissioned as a result of induction calls during April, May, and June, 1953, certain physicians completing internship this year and who were priority 1, 2, and 3 special registrants, reserve medical officers previously deferred or otherwise obligated, and volunteers.

The military departments now have a sufficient pool of reservists to fulfill the requirement of 1,150 physicians for the remainder of fiscal year 1954. This pool of reservists is comprised of physicians who volunteered for a commission and active duty during July and August, 1953, physicians who were commissioned as the result of the August, 1953, Selective Service call, and obligated reservists who were previously deferred. Included in the requirement of 1,150 physicians are the estimates of the military departments for a portion of next years' military intern class that will be recruited from senior medical students graduating during June, 1954. Prior to July, 1954, there is little likelihood, it is reported, of any calls being placed by the Department of Defense with the Selective Service System to bring special registrant physicians into the military service.

An estimated requirement of the armed forces for physicians to enter the military service during fiscal year 1955 is 5,300. These physicians will be supplied from priority 1 and 2 reservists and special registrants who have been deferred for essentiality or hardship; priority 3 special registrant physicians who became available in July, 1953, at the completion of their internships but who will not be brought to duty during fiscal year 1954; priority 3 special registrant physicians who will complete internship during June, 1954, and become available at that time; and priority 3 special registrant physicians who will be brought to duty as volunteers and as the result of Selective Service calls.

According to the best available information, there was a total of 2,234 nonveteran medical school graduates in 1952 and 2,791 in 1953. It is estimated that 1,800 of these graduates should be available for military service as priority 3 special registrants after June, 1953, and 2,230 after June, 1954. The number of physicians completing internships during June, 1953, who will be brought to duty during fiscal year 1954 is not known at this time; however, from available evidence the large majority of this group will remain to be called to duty as a result of Selective Service calls during fiscal year 1955. It can be estimated that well over half of the requirements of the armed forces for 5,300 physicians for fiscal year 1955 will be filled with priority 3 special registrant physicians who completed internships in June of 1953 and 1954, and a relatively small number of priority 1 and 2 special registrant and reserve physicians who may become available at that time. The remainder will be supplied from the priority 3 pool of special registrant physicians.

FIRST TEACHING INSTITUTE OF ASSOCIATION OF AMERICAN MEDICAL COLLEGES

During the week of October 19 to 23, just before its 64th annual meeting, the Association of American Medical Colleges conducted its first teaching institute at Atlantic City. The area covered included physiology, biochemistry, and pharmacology. Over a year of careful preliminary planning lay behind the institute, and this was undoubtedly largely responsible for its outstanding success as a unique experience for the delegates attending from the medical schools of the United States and Canada. Initial small groups, followed by larger group discussion and eventual summarization, covered such important topics as content of courses, interrelationships between basic medical science departments and between basic medical science and clinical departments, teachers, and, finally, teaching and learning techniques.

The free interchange of ideas and the sincere discussions of the complex and perplexing problems associated with the vast increase in current knowledge in basic medical sciences did much to create better perspective on the part of all who participated. The problems associated with bridging the still too wide gap between basic knowledge in physiology, biochemistry, and pharmacology and their clinical application to the diagnosis and care of patients as well as to the advance in knowledge through research were given careful consideration.

Much concern was evident in regard to the problems that the students face in this exciting and dynamic period of medical history. Careful reevaluation of course content, with particular emphasis on analysis of the relative merits of some phases of laboratory work in the basic medical sciences, indicated widespread dissatisfaction with the content, teaching methods, and techniques of many current programs. It was obvious that there is increasing dissatisfaction with traditional methods and that a stimulating experimental ferment has become evident in many of our medical schools. The desire to experiment continuously in an effort to make teaching more effective and learning opportunities more valuable and to avoid stereotyping of undergraduate medical education was evident throughout the entire institute.

It is to be hoped that the enthusiasm for self-evaluation and critical departmental and institutional analysis will be transmitted from the institute by the delegates and deans to their institutional colleagues as they return to their respective schools. Congratulations are due to the Association of American Medical Colleges for this foresighted progressive development of what is in essence a national faculty self-analysis in connection with their annual meetings. Subsequent institutes will undoubtedly prove to be equally effective in the respective areas that they will cover.

ORGANIZATION SECTION

SIXTH ANNUAL MEDICAL PUBLIC RELATIONS CONFERENCE

Hotel Jefferson, St. Louis

Monday, November 30, 1953

PROGRAM

REGISTRATION

9:00 a. m., Gold Room Foyer

OPENING SESSION

10:00 a. m., Gold Room

Chairman: Franklin L. Shively Jr., M.D., Dayton, Ohio, Vice-President, Montgomery County Medical Society

Address of Welcome

George F. Lull, M.D., Chicago, Secretary and General Manager, American Medical Association

Keynote Address: Facing Up to PR Facts

Walter B. Martin, M.D., Norfolk, Va., President-Elect, American Medical Association

MAKING A PR PROGRAM WORK

10:30 a. m., Gold Room

How My Society Does It

Josephine Renshaw, M.D., Washington, D. C., Chairman, Public Relations Committee, Medical Society of the District of Columbia

Clyde W. Miller, M.D., Wichita, Kan., Chairman, Public Relations Committee, Kansas State Medical Society

David Welton, M.D., Charlotte, N. C., President, Mecklenburg County Medical Society

Lewis A. Alesen, M.D., Los Angeles, Calif., Past President, California Medical Association

We'd Like to Know (Questions directed at symposium participants)

Charles S. Nelson, Columbus, Ohio, Executive Secretary, Ohio State Medical Association

William Alan Richardson, Rutherford, N. J., Editor, *Medical Economics*

Leo E. Brown, Chicago, Director of Public Relations, American Medical Association

LUNCHEON

12:30 p. m., Ivory Room

Toastmaster: Edwin S. Hamilton, M.D., Kankakee, Ill., Trustee, American Medical Association

What Motivates the Public's Feelings Toward Medicine

Leo H. Bartemeier, M.D., Detroit, Chairman, Committee on Mental Health, American Medical Association

SELLING OUR ECONOMIC SYSTEM:

HOW OTHERS DO IT

2:00 p. m., Gold Room

Chairman: E. Claude Bohrer, M.D., West Plains, Mo., President, Missouri State Medical Association

Howard W. Bennett, New York, Manager, Economic Education, Plant Community Relations Department, General Electric Company

Roger Fleming, Washington, D. C., Secretary-Treasurer, American Farm Bureau Federation

Questions and Discussion

MENDING OUR PR FENCES

3:00 p. m., Gold Room

Moderator: Rollen Waterson, Oakland, Calif., Executive Secretary, Alameda-Contra Costa County Medical Association

A National View

5:00 p. m., Adjournment of Conference

JOINT CONFERENCE ON MENTAL HEALTH

The American Medical Association, through its Committee on Mental Health, and the American Psychiatric Association jointly sponsored a conference on mental health in Washington, D. C., Oct. 24-25. This was the first time that representatives from more than 50 lay and medical organizations interested in mental illness had an opportunity to discuss together this major problem. Discussion was centered on four major topics: the educational process in training mental health workers, research, treatment, and prevention. Welcoming addresses were given by Dr. Walter B. Martin, President-Elect of the American Medical Association, and Dr. Kenneth E. Appel, president of the American Psychiatric Association. The main objective of the sponsoring organizations was brought out by Dr. Martin when he said: "There is a growing confidence in psychiatry and a mounting conviction that its principles need to be reintroduced into all phases of medical practice, to rehumanize medicine and, in this sense, return to medicine as a healing art. . . . This occasion may well mark the remarriage of partners, who should never have been divorced in the first place."

DR. LARSON RECEIVES PATHOLOGISTS' AWARD

Dr. Leonard W. Larson, Bismarck, N. D., a member of the A. M. A. Board of Trustees, recently received from the American Society of Clinical Pathologists a special award for outstanding contributions to pathology and to the society. The award is called a Scroll of Merit, which includes a medal and a certificate. Dr. Larson was the fourth member of the society to receive this award in its 32 years of existence. He has served for many years on the executive committee and has filled every office in the society during the last 25 years.

NEW HEART EXHIBIT

The pumping action of the heart and its valves are shown graphically in a new health education exhibit now available from the A. M. A.'s Bureau of Exhibits for showings to public groups. In this heart display, the sequence of events set in motion by exercise is demonstrated to show the circulation of the blood from the body to the heart, then through the lungs returning to the heart and back through the body again. Suggestions on how to prevent heart strain as well as symptoms of heart disease also are presented. This exhibit requires an extended space 20 feet long and 4 to 6 feet in depth. If space is limited, however, it may be shown in a booth 10 feet square. State and county societies may book the exhibit through the Bureau.

MEDICAL NEWS

ALABAMA

Joint Meeting of Physicians and Pharmacists.—Following a joint meeting, the physicians-pharmacists relations committees of the Alabama Medical Association and the Alabama Pharmaceutical Association adopted the following recommendations:

(1) That the widespread misuse of barbiturates and narcotics is deplorable and that the associations pledge continued vigorous and whole-hearted efforts further to protect the public health and aid in every way possible in stamping out these injurious practices.
(2) That continued education of both the physician and the pharmacist on the refilling of prescriptions under FDA regulations be undertaken.
(3) That no drug store name be used on prescription blanks and that the patient have freedom of choice of drug store in which the prescription should be filled.
(4) That joint meetings of physicians and pharmacists be held in every county and district to discuss mutual problems and encourage better relations.
(5) That doctors refrain from prescribing a little of every new item detailed to them and thereby help eliminate some of the druggists' problems.
(6) That druggists generally make a practice of using a nonrefill label strip on narcotic drugs.
(7) That a more uniform pricing of drugs be established.
(8) That a code of relations between physicians and pharmacists be considered and adopted for mutual progress to further protect the public health.

ARIZONA

New St. Joseph's Hospital.—On Aug. 17, St. Joseph's Hospital opened the doors of its new 6 million dollar building, which has a capacity of 325 beds, with piped-in oxygen at each bed. There are 10 operating rooms, 9 private labor rooms, and 4 delivery rooms; the emergency department consists of 3 operating and fracture rooms, a 4-bed recovery room, and a special emergency treatment room for patients with acute asthma. The outpatient department occupies one full wing of the building. A complete department of physical medicine and vocational rehabilitation is under the direction of a full time board-approved psychiatrist. St. Joseph's Hospital maintains an approved school of nursing and approved schools of medical technology and x-ray technology. With the opening of the new building, the old 198-bed St. Joseph's Hospital was closed.

New St. Joseph's Hospital in Phoenix

CALIFORNIA

Clinic for Hard-of-Hearing Children.—A diagnostic clinic for deaf and hard-of-hearing children has been opened at Childrens Hospital in Los Angeles. The new clinic will deal primarily with the total problem of the deaf child from the standpoint of medical care, possible corrective surgery, the communication problem, and psychological evaluation. Dr. Victor Goodhill is medical director of the clinic, which is located in a sound-treated suite in the Michael J. Connell Clinic building at Sunset Blvd. and Vermont Ave.

Personal.—Dr. Karl M. Bowman, professor of psychiatry, University of California Medical School, San Francisco, was recently awarded the honorary degree of doctor of science by Washburn University, Topeka, Kan.——Dr. Frederic J. Gaspard, who has practiced medicine in Los Angeles for more than 30 years, has been appointed as a member of the Los Angeles City Health Commission to succeed Dr. Francisco Bravo.——Dr. William M. Heidenreich was honored by his community in Arcadia when he retired from many years of service on the local board of education. After a testimonial dinner at the high school, a plaque was unveiled in the school's little theatre, which was dedicated as William M. Heidenreich Hall.——Dr. Robert Wartenberg, clinical professor of neurology, University of California Medical School, San Francisco, has been appointed honorary professor at the University of Freiburg, Germany, where he was a member of the faculty until 1935.——Dr. Bruce W. Halstead of the College of Medical Evangelists in Loma Linda has been invited to review the present status of fish poisoning in the Pacific for the eighth Pacific Science Congress, which will be held Nov. 16-28 at the University of the Philippines in Quezon City.

ILLINOIS

University Toxicology Service.—The University of Illinois College of Medicine, Chicago, reports that a total of 631 cases was handled during the 1952-1953 fiscal year by the division of toxicology of the department of pharmacology, with 491 cases handled for the coroner of Cook County. The university maintains a toxicological analytic service for law-enforcing agencies, physicians, and hospitals of the state. The service is available only to state's attorneys, hospitals, and physicians in Illinois. Services performed include blood alcohol, barbiturate, heavy metals, carbon monoxide poisoning, and alkaloidal analysis and a complete analysis if the cause of death is unknown. A nominal fee is charged for these services.

Dr. Vonachen Honored.—A citation for outstanding service in promoting the employment of physically handicapped persons was bestowed on Dr. Harold A. Vonachen, medical director of Caterpillar Tractor Company, Peoria, at a dinner sponsored by the Governor's Committee for Employment of the Physically Handicapped and the Disabled American Veterans at the LaSalle Hotel, Chicago, Oct. 4. The citation honors Dr. Vonachen for his work in pioneering the "Peoria Plan for Human Rehabilitation," which, first launched in 1942, established a national pattern, with other cities and towns throughout the country sending medical, industrial, and civic representatives to Peoria to study means of applying the program to their own communities. Representatives also came from England, Canada, Czechoslovakia, and Belgium. An outgrowth of the Peoria plan, the Institute of Physical Medicine and Rehabilitation of Peoria, a nonsectarian organization of which Dr. Vonachen is president, was established in 1951. Dr. Vonachen was presented with the William S. Knudsen award (1943-1944) for "outstanding work in the development of a program for the employment of handicapped Caterpillar workers which laid the foundation for a community-wide human rehabilitation program called 'The Peoria Plan for Human Rehabilitation.'" The Disabled American Veterans also honored Dr. Vonachen with a certificate of merit.

Chicago

Society News.—The Chicago Medical Society announces a dinner at 6:30 p. m., Nov. 17, at the Sheraton Hotel, 505 N. Michigan Ave., in honor of Dr. Joe V. Meigs, clinical professor, department of gynecology, Harvard Medical School, Boston, and Dr. Alan F. Guttmacher, clinical professor, obstetrics and gynecology, Columbia University College of

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Physicians and Surgeons, New York, who will be guest speakers at the joint meeting of the Chicago Medical Society and the postgraduate course in obstetrics and gynecology. At 8 p. m. Dr. Meigs will discuss "Fibromas of the Ovaries, the So-Called Meigs' Syndrome." Dr. Guttmacher will present "Conception Control: Modern Methods and Future Possibilities."

Board of Health Examinations.—The Chicago Civil Service Commission announces examinations for the following positions in the Chicago Board of Health: (1) chief medical officer ($10,000); (2) chief of division of laboratories ($10,000); (3) chief statistician ($10,000); (4) director in charge of drugs and biologics ($7,200); (5) chief of dental health section ($6,150); (6) bureau chief of communicable diseases ($6,120); and (7) chief bureau of child welfare ($6,120). Incumbents must reside in Chicago and be eligible to apply for any appropriate Illinois license. Application forms must be on file by Dec. 1, 4:30 p. m. Examinations will be held Dec. 5. For information, write or call Civil Service Commission, Room 208, City Hall, 121 N. LaSalle St.; RAndolph 6-8000, Ext. 582.

Panel on Hypertensive Cardiovascular Disease.—Dr. George E. Wakerlin will serve as moderator for a panel on hypertensive cardiovascular disease at a meeting of the Scientific Section of the Chicago Heart Association in Albert Dickinson Hall, Chicago Academy of Sciences, 2001 N. Clark St., Nov. 17, 8 p. m. His paper, "Pathogenesis of Hypertension," will be followed with "Treatment of Hypertension from a Surgeon's Viewpoint" by Dr. Loyal Davis and "Treatment of Hypertension from an Internist's Viewpoint" by Dr. Theodore N. Pullman. Dr. Louis N. Katz, who will open the discussion with "The Natural History of Untreated Hypertension," and Dr. William A. Thomas will serve as panel members. All professional members of the Chicago Heart Association are invited. Incoming telephone calls will be received at LIncoln 9-0606.

IOWA

Institute on Heart Diseases.—An institute on heart diseases under the joint sponsorship of the state department of health and the department of pediatrics and internal medicine, State University of Iowa College of Medicine, will be held at University Hospitals, Iowa City, Nov. 19, 1:30-9:30 p. m. The following program will be presented:

Lewis Thomas, Minneapolis, Research on the Pathogenesis of Rheumatic Fever.
Charles D. May, Iowa City, Rheumatoid Arthritis in Children.
Richard V. Ebert, Chicago, Physiology of the Circulation in Acute Infections.
William B. Bean, Iowa City, Clinical Problems in Aortic Stenosis.

The institute is open to all physicians. Opportunity will be given for inspection of the cardiovascular laboratory at the university.

MASSACHUSETTS

Chandler Ford Fund.—A fund of $40,000 has been established at the Boston University School of Medicine, to be known as the Chandler Ford Fund, for research in connection with diseases of the ear and the cure of deafness. The department of otolaryngology will make use of this fund according to the wishes of the late Mr. Chandler Ford, who made this bequest.

Society News.—The fall meeting of the Massachusetts Society of Examining Physicians will be held at the Harvard Club, Boston, Nov. 18, 6:30 p. m. After the dinner Dr. Paul R. Hawley, Chicago, director, American College of Surgeons, will speak on the subject, "Some Problems as They Affect the Profession, the Individual Doctor, and the Public." All physicians are cordially invited.

NEW JERSEY

Medical Alumni Day.—The sixth annual alumni-day meeting of the Jersey City Medical Center Alumni Association, Nov. 20, will open at 9:30 a. m. with a symposium on chronic infections, which will include the following presentations by Jersey City physicians:

Diagnosis and Management of Pyelonephritis, (Urology), Jacob D. Katz.
Chemotherapy of Pulmonary Tuberculosis, Samuel Cohen.
Subacute Bacterial Endocarditis, Bernard Eisenstein.
The Problem of Viral Hepatitis, Angelo M. Gnassi and Carroll M Leevy.

Memorial Day ceremonies will be held from 11:45 a. m. to 12:45 p. m., when the memorial lecture, "Diagnosis of Head and Neck Cancer in Children," will be delivered. From 3 to 4:30 p. m. surgery in infections will be discussed:

Experience with Generalized Peritonitis, Irving Marshall, Jersey City.
Current Concepts of Osteomyelitis, Leo E. Fischer, Jersey City.
Use of Varidase in Management of Surgical Infections, Manly B. Donaldson, New York.
The Problem of Infected Abortions, Victor Wagner, Jersey City.

NEW YORK

Society News.—"Respiratory Allergy in Infancy and Childhood" will be presented by Dr. Lewis Webb Hill, associate professor of pediatrics, Harvard Medical School, Boston, and will be discussed by Dr. Bret Ratner, professor of clinical pediatrics (allergy), New York Medical College, at a meeting of the section on allergy, Medical Society of the County of Kings and Academy of Medicine of Brooklyn (1313 Bedford Ave., Brooklyn 16) on Nov. 19, 9 p. m.

Meeting on Arthritis.—A postgraduate teaching day on arthritis and rheumatism was conducted at the Rochester Academy of Medicine, 1441 East Avenue, Rochester, Nov. 12, under the sponsorship of the arthritis and rheumatism committee of the Health Association of Rochester and Monroe County. Dr. Charles L. Steinberg, Rochester, served as chairman for the following program:

Differential Diagnosis of Rheumatoid Arthritis, Charles A. Ragan, New York.
Present-Day Treatment of Chronic Arthritis, Joseph Lee Hollander, Philadelphia.
Vascular Lesions in Rheumatoid Arthritis, Joseph J. Bunim, Bethesda, Md.

New York City

Harvey Lecture.—Dr. David Nachmansohn, Columbia University College of Physicians and Surgeons, will deliver the third Harvey lecture, "Metabolism and Function of the Nerve Cell," of the 1953-1954 series at the New York Academy of Medicine, Nov. 19.

Tumor Clinic.—Dr. Gray H. Twombly, professor of gynecology, New York University College of Medicine, will present "A Clinical Evaluation of Different Methods of Treatment of Cancer of the Cervix" at the tumor clinic conference at Harlem Hospital (Women's Pavilion, Main Floor, 137th St. Entrance), Nov. 18, 10:45 a. m.

The Salmon Lectures.—The final lecture of the 21st series of the Thomas William Salmon lectures on cultural and mental disorders will be "Culture and Hysteria" by Ralph Linton, Ph.D., Sterling Professor of Anthropology, Yale University, New Haven, Conn., Nov. 17, 8:30 p. m., at Hosack Hall, New York Academy of Medicine, 2 E. 103rd St.

OHIO

Industrial Medicine Program.—A symposium, "Dangers of Solvent Handling," will be presented before the section on industrial medicine and hygiene of the annual Greater Cincinnati Safety Conference, Nov. 17. The speakers include Floyd A. Van Atta, Ph.D., director of industrial hygiene, National Safety Council, Chicago, whose topic is "Toxicity of Solvents"; Dr. Edward A. Gall, professor of pathology, University of Cincinnati College of Medicine, who will discuss "The Effects of Solvent Absorption on the Human Body"; and Dr. Donald J. Birmingham, division of occupational health, U. S. Public Health Service, Washington, D. C., who will present "The Effects of Solvents on Human Skin." A panel discussion and question period on safe handling of solvents will complete the program. Co-chairmen for the section meeting in Parlor H, Hotel Sheraton-Gibson, 2:15

to 4:15 p. m., are Dr. James P. Hughes, Bureau of Industrial Health of the Cincinnati Health Department, and Miss Margaret Carnine, R.N., Trailmobile, Inc. Members of the medical and nursing professions are cordially invited to attend the conference and to participate in the discussion period at the meeting of the section on industrial medicine and hygiene.

PENNSYLVANIA

Mellon Lecture.—Dr. Paul Gyorgy, chief of service, department of pediatrics, Hospital of the University of Pennsylvania, Philadelphia, will deliver the 37th Mellon lecture, "Some Aspects of Protein Nutrition," before the Society for Biological Research of the University of Pittsburgh School of Medicine, Nov. 20.

WASHINGTON

Course on Advances in Drug Therapy.—A course on recent advances in drug therapy will be given in the Health Sciences Building, University of Washington School of Medicine, Seattle, Nov. 20-21, under the sponsorship of the university, the Washington State Medical Association, and the Washington State Department of Health. Friday will be devoted to discussions of metabolic disorders, infectious diseases, gastrointestinal diseases, and hematology, and Saturday to diseases of the nervous system and cardiovascular diseases.

PHILIPPINE ISLANDS

Pacific Science Congress.—The eighth Pacific Science Congress of the Pacific Science Association will convene at the University of the Philippines, Quezon City, Nov. 16-28, under the auspices of the Republic of the Philippines and the National Research Council of the Philippines. The section on public health will present (1) progress reports and panel discussions on specific public health problems, including malaria, schistosomiasis japonica, Bancroftian filariasis, yaws, and other diseases important to Pacific areas; and (2) progress reports and seminars on rural health and sanitation, including recruitment and training of personnel. The section on nutrition will discuss the place of nutrition education in the public health program; high protein substitutes for milk in child feeding; urinary excretion of thiamine and riboflavin of Filipinos; and the relationship between dietary intake and serum levels of vitamin A and carotene.

GENERAL

Fellowship in Pediatric Neurology.—One year's fellowship in pediatric neurology is now available in the Julian D. Levinson research foundation in conjunction with the children's division of the Cook County Hospital, Chicago; salary $3,500. For details communicate with Dr. Abraham Levinson, Children's Division, Cook County Hospital, Chicago 12.

Annual Cerebral Palsy Meeting.—United Cerebral Palsy has scheduled its fourth annual convention for Nov. 13-15 at the Hotel New Yorker in New York. Physicians who will deliver addresses include: Bronson Crothers and Sidney Farber, Boston; Samuel M. Wishik, Pittsburgh; Charles F. McKhann, Philadelphia; H. Houston Merritt, New York; and Glidden L. Brooks, Pittsburgh, UCP medical director.

Meeting on Electronic Instrumentation.—The annual conference on electronic instrumentation and nucleonics in medicine will be held at the New Yorker Hotel in New York, Nov. 19-20, under the sponsorship of the American Institute of Electrical Engineers, Institute of Radio Engineers, and the Instrument Society of America. Recent advances in instrumentation for x-ray motion pictures, the use of ultrasonic waves in the visualization of soft tissue structures and cancer, analytical methods in blood serum determinations, and other papers on medical instrumentation will be presented.

Industrial Hygienists Meet in Pittsburgh.—The 18th annual meeting of the Industrial Hygiene Foundation will be held at the Mellon Institute, Pittsburgh, Nov. 18-19. Dr. Oscar A. Sander, Milwaukee, chairman, medical committee, will be chairman of a conference on trends in industrial medicine Wednesday morning. The program will open with the presentation, "The Proper Scope of Medical Care in Industry," by Dr. Carl M. Peterson, Secretary, A. M. A. Council on Industrial Health, and discussion by Dr. Joseph H. Chivers, Chicago. Other papers will be presented as follows:

The Stress Disorders, William P. Shepard, New York; discussion, Dr. Samuel T. Nicholson Jr., Pottstown, Pa.

Problems Associated with Older Workers, Charles E. Dutchess, New York; discussion, Edward M. Kline, Cleveland.

Compensation for Residual Disability, Clarence D. Selby, Ann Arbor, Mich.; discussion, Edward H. Carleton, East Chicago, Ind.

Dr. Sander will also serve as chairman for the joint medical-legal conference Wednesday afternoon, and he and Dr. James P. Hughes, Cincinnati, will participate in a panel discussion, "Administration of Workmen's Compensation Laws."

New England Diabetes Fair.—The diabetes fair, sponsored by the New England Diabetes Association, will be held Nov. 16-17 during National Diabetes Week, at Horticultural Hall, Boston, from 11 a. m. to 10 p. m. The committee consists of Dr. Harry Blotner, Boston, chairman, and Drs. Frank N. Allan, Boston, Charles W. Finnerty, Somerville, Mass., and Alexander Marble and Howard F. Root, Boston, and the association officers, Dr. Richard P. Stetson, Boston, president; Dr. Reed Harwood, Boston, vice-president; Dr. Lewis Tillman McDaniel, Brookline, Mass., treasurer; and Dr. Charles C. Bailey, Boston, secretary. To stimulate the interest of the public concerning diabetes, there will be exhibits illustrating various phases of diabetes and its management: pharmaceuticals, dietetics, social and public service aids, diabetes camps, insurance for diabetics, diabetes detection in certain communities, nursing care in the hospital and home, books and pamphlets on diabetes, and charts illustrating medical and surgical features of diabetes. Motion pictures will be presented throughout the day. Lecture programs in the afternoon and evening of both days will feature panel discussions on diabetes. X-rays of the chest will be available, and facilities will be provided for urine sugar and blood sugar testing to be made while the subjects watch the procedure. Physicians, medical students, nurses, social workers, the public at large, and other interested groups are invited to attend the fair.

LATIN AMERICA

Centennial in São Paulo.—For the fourth centennial of its founding, the city of São Paulo, capital of the state of São Paulo, Brazil, is planning a series of cultural events that will include meetings of medical interest. Scheduled for April, 1954, is the International Congress of Surgery of the International College of Surgeons; for July, the International Cancer Congress, International Cardiological Congress, International Congress on Oto-Neuro-Ophthalmology, Pan American congresses of gastroenterology and on puericulture and pediatrics, South American Congress of Angiology, which will deal with the etiopathogenesis, medical and surgical treatment of arteriosclerosis obliterans, and Latin American congresses on gynecology and obstetrics and on mental health; for November, the 10th International Congress on Medicinal and Similar Plants. Information may be obtained from the secretary, Associação Paulista de Medicina, Caixa Postal 2103, São Paulo, Brazil, or from the Committee on the Fourth Centennial of the City of São Paulo, Rua 24 de Maio, 250-7° andar, São Paulo, Brazil, S. A.

FOREIGN

London Medical Exhibition.—An annual medical exhibition will be held at the New Horticultural Hall, Greycoat St., Westminster, Nov. 16-20, for display of the latest developments in pharmaceutical research, ethical medical products, surgical instruments, hospital equipment, etc. Members of the public are not admitted, but a special welcome is extended to members of the medical profession in America and other overseas countries. Information may be obtained from the organizers, The British & Colonial Druggists Ltd., 194-200, Bishopsgate, London, E.C.2., England.

DEATHS IN OTHER COUNTRIES

Dr. René Sand, an honorary member of the American Medical Association, died Aug. 23 in Brussels, Belgium, at the age of 76. Dr. Sand, who was the founder of the Belgium Social Medicine Association in 1912, founded the International Hospitals Association in 1929 and was its first president, and served also as president of its postwar successor, the International Hospital Federation, from its foundation in 1947 to his death. He was technical adviser to the League of Red Cross Societies from 1921 to 1936 and secretary-general of the Belgium Ministry of Health from 1937 to 1940, when he was captured by the Nazis and imprisoned in Tyrol, Austria, where in 1945 he was liberated by the U. S. Seventh Army. Dr. Sand presided over a committee of experts assembled by the UN in Paris in 1946 to draft an international health organization, and in 1950 he was appointed chairman of the World Health Organization expert committee on professional and technical education. He recently served as chairman of the 8th International Hospital Congress in London. After World War II Dr. Sand was the first occupant of a chair of social medicine established in the University of Brussels with the support of the Rockefeller Foundation. He founded the Belgium Committee on Social Work and the International Conference on Social Work and was recently elected the first president of the Societé Belge de Droit International Médical, which is dedicated to the study and development of international medical law. An honorary member of the American Hospitals Association and the New York Academy of Medicine, Dr. Sand was awarded the Leon Bernard Foundation prize in 1951. He was to have been one of the vice-presidents of the First World Conference on Medical Education held recently in London, but illness prevented his attendance. News of his death reached London while the conference was in progress.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

COLORADO:* *Examination.* Denver, Dec. 15-16. *Final date for filing* application is Nov. 14. Executive Secretary, Miss Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

DELAWARE: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

FLORIDA:* *Examination.* Jacksonville, Nov. 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

GUAM: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

HAWAII: Honolulu, Jan. 11-14. *Examination.* Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

IDAHO: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

IOWA:* *Examination.* Des Moines, Dec. 7-9. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

KANSAS: Topeka, Dec. 9-10. Sec., Dr. O. W. Davidson, 864 New Brotherhood Bldg., Kansas City.

KENTUCKY: *Examination.* Louisville, Dec. 7-9. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville.

MARYLAND: *Examination.* Baltimore, Dec. 8-11. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore 1.

MISSISSIPPI: *Reciprocity.* Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

NEBRASKA:* *Examination.* Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

NORTH DAKOTA: *Examination.* Grand Forks, Jan. 6-9, 1954. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

OHIO: *Examination.* Columbus, Dec. 17-19. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

OKLAHOMA:* *Examination.* Oklahoma City, June 9-10. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

PENNSYLVANIA: *Examination.* Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

SOUTH DAKOTA:* *Examination.* Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

TEXAS: Fort Worth, Nov. 12-14. Reciprocity applicants must be completed 30 days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

UTAH: *Examination and Reciprocity.* Salt Lake City, Nov. 17. Director, Mr. Frank E. Lees, 314 State Capitol, Salt Lake City 1.

VERMONT: *Examination.* Burlington, Feb. 1954. Sec., Dr. P. J. Lawliss, Richford.

VIRGINIA: *Examination.* Richmond, Dec. 3-5. *Reciprocity.* Richmond, Dec. 2. Address: Board of Medical Examiners, 631 First St. S.W., Roanoke.

WISCONSIN:* *Examination and Reciprocity.* Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: *On application.* Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

OKLAHOMA: *Examination.* Oklahoma City, April 16-17. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination.* Portland, Dec. 5. Sec., Dr. Charles D. Byrne, University of Oregon, Eugene. (Examinations during 1954 will be held in Portland on March 6, June 5, Sept. 11 and Dec. 4.)

SOUTH DAKOTA: *Examination.* Vermillion, Dec. 4-5. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

WISCONSIN: *Examination.* Milwaukee, Dec. 5. Final date for filing application is Nov 27. *Madison, April 3. Final date for filing application* is March 26. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

World Congress of Cardiology, Washington, D. C., and Bethesda, Md., U. S. A., Sept. 12-17, 1954. Dr. L. W. Gorham, 44 East 23d St., New York 10, N. Y., U. S. A., Secretary-General.

World Congress of International Society for the Welfare of Cripples, The Hague, Netherlands, Sept. 13-17, 1954. For information write: D. C. Schaap, Centrale Vereniging, Apeldoorschweg 51, Arnhem, Netherlands.

World Federation of Occupational Therapists, Edinburgh, Scotland, August 17, 1954.

World Medical Association, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

DEATHS

Sabin, Florence Rena ⊕ died at her home in Denver, Oct. 3, aged 81. Dr. Sabin was born in Central City, Colo., Nov. 9, 1871. She received her degree in medicine in 1900 from Johns Hopkins University School of Medicine, Baltimore, where she had the distinction of being the first woman to be admitted and graduated, and later the first woman to hold a full professorship. Dr. Sabin was also the first woman intern at Johns Hopkins Hospital in 1900-1901; she then joined the faculty as assistant in anatomy, subsequently becoming an associate and associate professor and professor of histology. She was, in 1925, the first woman to be invited to join the staff of the Rockefeller Institute for Medical Research in New York and served until 1938, when she became an emeritus member. She then returned to Denver and later became a chairman of the health section of the state's post-war planning committee, head of the state subcommittee on health, and city manager of health and charities for Denver. She was the first woman to become an honorary member of the New York Academy of Science and a member of the American Academy of Sciences. Dr. Sabin was president of the board of the Finney-Howell Research Foundation, past president of the Western Branch of the American Public Health Association, a member of the American Association of Anatomists, of which she was first woman vice-president, 1908-1909, and the first woman president, 1924-1926, American Association of Physiologists, the Society of Experimental Biology and Medicine, serving as councilor in 1932, and the National Tuberculosis Association. She was honorary life-member of the Harvey Society, American Association for the Advancement of Science, the Colorado State Medical Society, and American Association of University Women and was elected a director of the American Society for the Control of Cancer. In 1943 she was made an honorary national commander of the Women's Field Army. Dr. Sabin was the winner of the *Pictorial Review* 1928 achievement award of $5,000, for contributions to medical science. In 1932 she received the first national achievement award conferred by the Chi Omega Sorority and in 1935 was awarded the $5,000 M. Carey Thomas prize by Bryn Mawr (Pa.) College. In recent years she received the Trudeau medal of the National Tuberculosis Association for her "extensive studies of the physiologic activities of the chemical fractions of the tubercle bacillus," the first Jane Addams medal for distinguished service by an American woman, a Lasker Foundation award for her achievements as leading spirit in public health programs in Colorado, the American Woman's Association medal for eminent achievement, the Elizabeth Blackwell citation of the New York Infirmary, and an American Brotherhood Arts and Sciences citation. She was awarded the General Rose Memorial Hospital's 1951 medal for distinguished public service. In 1951 she was honored at ceremonies at which the new cancer wing at the University of Colorado Medical Center was dedicated as the Florence R. Sabin Building for Research in Cellular Biology. On this occasion, her colleagues honored her at a dinner and presented her with a bound volume of felicitations from all parts of the country. Dr. Sabin had honorary degrees from many universities; she wrote extensively for scientific publications, was on the editorial board of the *Anatomical Record,* and was the author of "An Atlas of the Medulla and Mid-Brain."

Siegler, Samuel Lewis ⊕ Brooklyn; born in Brooklyn Nov. 11, 1894; Fordham University School of Medicine, New York, 1918; specialist certified by the American Board of Obstetrics and Gynecology; member of the Endocrine Society; fellow of the American College of Surgeons, American Society for the Study of Sterility, British Society for the Study of Sterility, Brooklyn Gynecological Society and the New York Academy of Medicine; past president of the East New York Medical Society; vice-president of the New York Society for the Study of Sterility; honorary fellow of the Argentina Society for Study of Sterility; in January, 1945, at the annual meeting of the Planned Parenthood Federation of America he was cited for his volume on "Human Fertility in the Female" as a contribution to the diagnosis and treatment of infertility in women; this book was translated into Spanish, French, and Italian; attending obstetrician and gynecologist, Brooklyn Women's Hospital; director of obstetrics and gynecology, Unity Hospital; assistant attending in obstetrics and gynecology, Greenpoint Hospital; associate staff, Jewish Hospital; produced the motion pictures, "Sterility, Its Causes, Investigation and Treatment" and "Ovulation with Pregnant Mare's Serum"; served during World War I; on the editorial board of *Fertility and Sterility*; died in the Long Island College Hospital Sept. 15, aged 58, of encephalomyelitis.

Thompson, Ira Fay ⊕ Beloit, Wis.; born in Lawrence, Ill., Oct. 1, 1877; Bennett College of Eclectic Medicine and Surgery, Chicago, 1900; member of the American Public Health Association; elected to the board of directors in 1937 of the Wisconsin Anti-Tuberculosis Association of which he was president from 1945 to 1948, and a member of the senior council at the time of his death; served as vice-president and president of the state board of health; for several years worked with the state board of health, serving as deputy state health officer from 1916 to 1919, as organizer and director of the bureau of venereal diseases from 1919 to 1922, and as deputy and later acting health commissioner of the Milwaukee health department from 1922 to 1925; for seven years worked with the Milbank Health Foundation as assistant to the health commissioner in Syracuse, N. Y.; on his return to Wisconsin in 1932, served as Racine health commissioner until 1945; at one time on the faculty of Marquette University School of Medicine; died July 5, aged 75, of cerebral hemorrhage.

Taquino, George James ⊕ New Orleans; born in New Orleans Oct. 19, 1884; Medical Department of Tulane University of Louisiana, New Orleans, 1911; specialist certified by the American Board of Otolaryngology; professor of otorhinolaryngology and head of the department at Louisiana State University School of Medicine; served during World War I; member of the Southeastern Surgical Congress, American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otological Society, and the American Broncho-Esophagological Association; fellow of the International College of Surgeons and the American College of Surgeons; consulting bronchoscopist, U. S. Public Health Service; received the honorary doctor of science degree from Loyola University of the South in 1942; affiliated with Charity Hospital of Louisiana, Touro Infirmary and Hotel Dieu, Sister's Hospital, where he died Aug. 29, aged 68, of dissecting aneurysm of the aorta.

Soper, Horace Wendell ⊕ St. Louis; born in Hillsboro, Ill., in 1867; Washington University School of Medicine, St. Louis, 1894; specialist certified by the American Board of Internal Medicine; an Affiliate Fellow of the American Medical Association; member of the American Gastro-Enterological Association; fellow of the American College of Physicians; past president of the Missouri chapter of the National Society for the Advancement of Gastro-Enterology; past president of the National Gastro-Enterological Association; secretary of the Section on Gastro-Enterology and Proctology of the American Medical Association from 1917 to 1920 and chairman, 1921-1922; consultant, De Paul and St. Luke's hospitals, co-founder of the Soper Mills Clinic; author of "Clinical Gastroenterology"; died in Barnes Hospital Sept. 28, aged 86, of heart disease.

De Lamater, Hasbrouck ⊕ St. Joseph, Mo.; born Jan. 12, 1870; Medical College of Alabama, Mobile, 1901; an Associate Fellow of the American Medical Association; past president of the Buchanan County Medical Society; director of

---

⊕ Indicates Member of the American Medical Association.

hygiene with city public schools from 1916 until his retirement in 1942 when he received the William A. Howe award from the American School Health Association for his outstanding service in school health work; fellow of the American Public Health Association; a charter member of the American Association of School Physicians; affiliated with St. Joseph's Hospital and the Missouri Methodist Hospital, where he died Sept. 24, aged 83, of cardiac decompensation.

Murphy, John Francis ⊕ Providence, R. I.; born in Woonsocket, R. I., Jan. 22, 1901; University of Pennsylvania School of Medicine, Philadelphia, 1927; specialist certified by the American Board of Obstetrics and Gynecology; member of the New England Obstetrical and Gynecological Society; instructor in obstetrics at Harvard Medical School in Boston; affiliated with Rhode Island, Charles V. Chapin, and Providence Lying-In hospitals; on the courtesy staffs of the Memorial Hospital, Pawtucket, and the Roger Williams and St. Joseph's hospitals; died Aug. 30, aged 52, of hypertensive cardiovascular disease.

Smith, Clarence Austin ⊕ Seattle; born in Derby, Conn., Jan. 24, 1861; College of Physicians and Surgeons, medical department of Columbia College, New York, 1887; an Associate Fellow of the American Medical Association; fellow of the American College of Physicians; president of the King County Medical Society in 1898 and the Washington State Medical Association in 1909; from 1896 to 1898 a member of the Washington Board of Medical Examiners; formerly city health officer; editor emeritus of *Northwest Medicine,* which he helped to found in 1903 when he became editor; died Sept. 10, aged 92, of chronic myocarditis.

Newberger, Charles ⊕ Chicago; born Oct. 13, 1883; Rush Medical College, Chicago, 1909; assistant professor of obstetrics and gynecology emeritus at the University of Illinois College of Medicine; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; served as consultant for the maternity division, maternal and child health, Illinois State Department of Public Health; senior attending obstetrician at Mount Sinai Hospital, where he died Sept. 25, aged 69, of acute myocardial infarction.

Aurin, Emil Carl, Fort Ogden, Fla.; Eclectic Medical Institute, Cincinnati, 1897; died Aug. 18, aged 77, probably of coronary occlusion.

Baldwin, William Sherman, East St. Louis, Ill.; Jenner Medical College, Chicago, 1907; died in St. Mary's Infirmary in St. Louis Aug. 1, aged 77.

Bancroft, George Raymond Jr. ⊕ Kennebunk Port, Maine; Tufts College Medical School, Boston, 1944; certified by the National Board of Medical Examiners; died Aug. 14, aged 33, of coronary occlusion.

Bellehumeur, David Stanislaus ⊕ St. Petersburg, Fla.; Laval University Medical Faculty, Montreal, Canada, 1896; member of the Massachusetts Medical Society; died in Mound Park Hospital Aug. 20, aged 72, of fracture of the right shoulder and the right hip received in a fall.

Bennet, Pearl R., Terre Haute, Ind.; Eclectic Medical Institute, Cincinnati, 1905; died in Danville, Ill., July 4, aged 75.

Bitten, Robert Mooney ⊕ Jersey City, N. J.; College of Physicians and Surgeons, Boston, 1929; Université Catholique de Louvain Faculté de Médecine, Belgium, 1930; member of the American Society of Anesthesiologists, Inc.; affiliated with Greenville and Margaret Hague Maternity hospitals; died in the Medical Center Sept. 16, aged 56, of metastatic carcinoma of the lumbar spine.

Black, Glenn Raymond ⊕ Franklin Township, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1949; died Aug. 31, aged 31, of accidental drowning.

Blechman, Elihu David, Miami Beach, Fla.; University of Pennsylvania School of Medicine, Philadelphia, 1927; died Aug. 27, aged 50, of coronary thrombosis.

Bond, Van H. ⊕ Hornersville, Mo.; Missouri Medical College, St. Louis, 1893; died in the Dunklin Memorial Hospital in Kennett, Sept. 4, aged 83.

Bryans, Charles Iverson ⊕ Augusta, Ga.; University of Georgia School of Medicine, Augusta, 1904; professor emeritus of clinical ophthalmology and otolaryngology at his alma mater, where he was a member of the faculty since 1905; for many years affiliated with University and Wilhenford hospitals; died July 18, aged 70, of cerebral thrombosis.

Burbridge, Leonidas T., New Orleans; Meharry Medical College, Nashville, Tenn., 1893; died Sept. 14, aged 83.

Cameron, Donald Archibald, Royal Oak, Mich.; Detroit College of Medicine, 1915; served during World War I; died in Charlevoix Sept. 6, aged 64, of chronic nephritis and coronary thrombosis.

Challed, Don Sheridan ⊕ Cedar Rapids, Iowa; State University of Iowa College of Medicine, Iowa City, 1928; member of the American Society of Anesthesiologists; past president of the Linn County Medical Society; served during World War II; formerly health officer; affiliated with Mercy Hospital and St. Luke's Methodist Hospital, where he died Sept. 14, aged 48, of portal cirrhosis.

Cobb, Benjamin Elden, Unionville, Mo.; St. Louis University School of Medicine, 1912; died Aug. 25, aged 73, of uremia and chronic myocarditis.

Comerer, Jacob Alvin, Allentown, Pa.; Baltimore Medical College, 1897; died Sept. 5, aged 85, of arteriosclerosis.

Crawford, James Howard ⊕ Columbiana, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1921; in 1930 was chosen Shelby County's "Man of the Year"; died in Valdosta, Ga., Sept. 19, aged 59, of coronary occlusion.

Criscillo, Serafino Lewis ⊕ New York City; New York Medical College, Flower and Fifth Avenue Hospitals, New York, 1931; died Aug. 15, aged 49, of left ventricular failure.

Derbyshire, Albert L. ⊕ San Francisco; Medical College of Indiana, Indianapolis, 1886; served as acting assistant surgeon in the U. S. Public Health Service Reserve; died Sept. 5, aged 102, of bronchopneumonia and arteriosclerosis.

Duncan, Marion W., Centerton, Ark.; Memphis (Tenn.) Hospital Medical College, 1899; died Sept. 8, aged 84, of congestive heart disease.

Einhorn, Max ⊕ New York City; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Germany, 1884; an Associate Fellow of the American Medical Association; member of the American Association for Thoracic Surgery; former professor of medicine at the New York Post-Graduate Medical School and Hospital; consultant at the Lenox Hill Hospital, where he died Sept. 25, aged 91.

Fleming, Charles LeRoy ⊕ Penns Grove, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1906; consulting member of the staff of the Salem County Memorial Hospital in Salem; an official of the Penns Grove National Bank and Trust Company, where he served on the board of directors for several years; died Sept. 13, aged 68, of cerebral hemorrhage.

Fraden, William, New York City; University and Bellevue Hospital Medical College, New York, 1923; served during World War II; died in August, aged 52.

Gates, Ira Norman ⊕ Seattle; University of Vermont College of Medicine, Burlington, 1906; an Associate Fellow of the American Medical Association; affiliated with Virginia Mason Hospital, where he died Sept. 5, aged 76.

Gilmore, Howard Manning ⊕ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1921; member of the American Society of Anesthesiologists; on the staff of Mount Carmel Hospital, where he died Sept. 11, aged 58.

Gould, Arthur L. ⊕ Freeport, Maine; Medical School of Maine, Portland, 1905; health officer; affiliated with Brunswick (Maine) Hospital; drowned in Luther Pond near Jackman July 3, aged 70, when he fell from a canoe while fishing.

Gregory, Lorenzo Theophilus, Kershaw, S. C.; Medical College of the State of South Carolina, Charleston, 1896; served as mayor and as chairman of the school board; director of the Bank of Kershaw and the Springs Cotton Mills; died July 28, aged 83, of chronic emphysema of the lungs.

Henry, Frank Charles, Verona, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; formerly coroner of Middlesex County, and New Jersey Assemblyman; served as health officer of Perth Amboy; practiced in Perth Amboy, where he was affiliated with Perth Amboy Hospital, where he died Aug. 31, aged 82, of carcinoma of the sigmoid.

Hewitt, John Michael ⊕ Major, U. S. Army, retired, Los Angeles; Niagara University Medical Department, Buffalo, 1889; formerly professor of military science and tactics at Cornell University Medical School in New York; served during World War I; entered the medical corps of the U. S. Army as a first lieutenant in 1917 and retired Sept. 30, 1931, by operation of law; died July 26, aged 85, of carcinoma of the esophagus.

Howland, Charles Francis, Westfield, N. J.; Fordham University School of Medicine, New York, 1916; served in France with the American Expeditionary Forces during World War I; died Sept. 22, aged 79.

Johnston, Harold Alvah, Ingomar, Pa.; University of Pittsburgh School of Medicine, 1931; died in the Allegheny General Hospital, Pittsburgh, July 28, aged 46.

Johnstone, Charles William ⊕ Du Bois, Pa.; College of Physicians and Surgeons, Baltimore, 1906; affiliated with Du Bois and Maple Avenue hospitals; died July 30, aged 72, of carcinoma of the lung.

Jones, Mortimer Dunham, Ridgewood, N. J.; Columbia University College of Physicians and Surgeons, New York, 1900; medical superintendent of the Kings County Hospital in Brooklyn from 1910 to 1929, when he became medical superintendent of the New York City Hospital, Welfare Island; died Sept. 21, aged 76, of coronary occlusion.

Kalayjian, Dikran Sarkis ⊕ Detroit; Rush Medical College, Chicago, 1902; an Associate Fellow of the American Medical Association; member of the South Dakota State Medical Association; died Aug. 10, aged 86, of carcinoma of the colon.

Katzman, George Manual ⊕ Philadelphia; University of Illinois College of Medicine, Chicago, 1926; affiliated with the regional office of the Veterans Administration; died Aug. 30, aged 52, of coronary insufficiency.

Keeling, Irene Cutter ⊕ Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, Kan., 1929; affiliated with University of Kansas Medical Center, Kansas City, Kan., and Kansas City General Hospital; died in Research Hospital, Sept. 29, aged 54, of ulcerative ileocolitis.

Kimmelman, Simon ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1902; died Sept. 26, aged 78, of coronary occlusion.

Knapp, Charles Whittemore ⊕ Newtown, Conn.; Columbia University College of Physicians and Surgeons, New York, 1912; formerly on the faculty of his alma mater; served overseas during World War I; formerly practiced in Greenwich, Conn., where he was chairman of the board of health, on the staff of St. Luke's Convalescent Hospital and Greenwich Hospital, where he was chief of staff and where he died Sept. 14, aged 68, of pulmonary edema.

Laslie, Carney Graham ⊕ Montgomery, Ala.; College of Physicians and Surgeons, Baltimore, 1903; died Sept. 14, aged 75, of coronary thrombosis.

Levy, Erich L. ⊕ New York City; Friedrich-Wilhelms Universität Medizinische Fakultät, Berlin, Germany, 1927; affiliated with Jewish Memorial Hospital and Medical Arts Hospital in New York City and Queens General Hospital in Jamaica, where he died Sept. 9, aged 52.

Lynch, Richard Alphonsus, Boston; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1919; physician for the Shubert theatres for many years and composer of several songs; died Sept. 9, aged 63.

McBryde, Malcolm Hugh, Reidsville, N. C.; University College of Medicine, Richmond, 1901; died in the Annie Penn Memorial Hospital July 14, aged 75, of cerebral thrombosis.

McCord, Ollie Hagan ⊕ Woodruff, S. C.; Atlanta School of Medicine, 1910; died July 25, aged 67, of arteriosclerosis.

MacKenzie, Oliver Reynolds ⊕ Walled Lake, Mich.; Marquette University School of Medicine, Milwaukee, 1935; died Sept. 17, aged 44, of injuries received in an automobile accident.

Malloch, Thomas Archibald, White Plains, N. Y.; McGill University Faculty of Medicine, Montreal, 1913; M.R.C.P., London, 1919; F.R.C.P., London, 1930; served with the Canadian Army during World War I; for many years librarian of the New York Academy of Medicine; author and editor of several books; died in Tarrytown (N. Y.) Hospital Sept. 19, aged 66, of myocardial infarction and coronary thrombosis.

Martin, William Riley, New Bern, N. C.; Howard University College of Medicine, Washington, D. C., 1925; died Aug. 22, aged 56, of coronary thrombosis.

Maxwell, George Madison ⊕ Roanoke, Va.; North Carolina Medical College, Davidson, 1901; Jefferson Medical College of Philadelphia, 1906; fellow of the International College of Surgeons; served during World Wars I and II; died in the Veterans Administration Hospital Sept. 24, aged 77.

Meigs, Benjamin Lyle, Long Beach, Calif.; State University of Iowa College of Medicine, Iowa City, 1902; served during World War I; formerly affiliated with Long Beach Community and Seaside Memorial hospitals; died in the Harriman-Jones Clinic Hospital Sept. 15, aged 74, of carcinoma of the colon.

Meredith, Charles James ⊕ Valley City, N. D.; University of Manitoba Faculty of Medicine, Edmonton, Alberta, Canada, 1921; fellow of the American College of Surgeons; affiliated with Mercy Hospital; died Sept. 20, aged 58.

Miles, William Clinton ⊕ Griffin, Ga.; Atlanta College of Physicians and Surgeons, 1908; past president of the Spalding County Medical Society; served during World War I; died July 12, aged 71, of arteriosclerosis.

Miller, Elmer Manton ⊕ Woodsville, N. H.; Baltimore Medical College, 1898; died July 1, aged 80, of coronary sclerosis.

Milliken, Howard Augustus ⊕ Hallowell, Maine; Medical School of Maine, Portland, 1899; died in the Augusta General Hospital in Augusta, recently, aged 79, of ruptured esophageal varices.

Minahan, Thomas, Niles, Ohio; Cleveland Homeopathic Medical College, 1898; died Sept. 6, aged 91, of hypostatic pneumonia.

Moosey, Marye Maxine, Tacoma, Wash.; University of Pittsburgh School of Medicine, 1951; resident at St. Joseph's Hospital; died July 13, aged 36, of injuries received in an automobile accident.

Moxey, Albert Frankish ⊕ Havertown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1906; for many years practiced in Philadelphia, where he was supervisor of the public schools and served on the staffs of the Temple University, Memorial and Episcopal hospitals; affiliated with the Hospital of the University of Pennsylvania in Philadelphia, where he died Sept. 20, aged 69, of leukemia.

DIED WHILE IN MILITARY SERVICE

McCaslin, Hugh Towles, Cincinnati; Columbia University College of Physicians and Surgeons, New York, 1952; interned at Cincinnati General Hospital; first lieutenant in the medical corps of the U. S. Air Force; killed in an automobile accident at Randolph Air Field Base, Texas, Sept. 1, aged 25.

GOVERNMENT SERVICES

MEDICAL AND HEALTH BUDGETS OF FEDERAL AGENCIES

The federal government operates or participates in more than 60 health, medical, and related programs scattered among at least 19 different departments, independent agencies, or commissions. The cost is in excess of $1,775,882,197 this fiscal year. A breakdown of the budgets follows:

Department of Health, Education and Welfare ($340,553,000 Total)

Office of Vocational Rehabilitation—$23,655,500

The bulk of this appropriation will be apportioned to states having programs furnishing handicapped persons with medical examinations, surgical and therapeutic treatment, hospitalization, prosthetic appliances, occupational tools and aids, vocational training, and funds for maintenance. The states are required to match these federal grants on a dollar-for-dollar basis.

Food and Drug Administration—$6,250,000

This appropriation is used to enforce laws designed to protect the consuming public against adulteration and misbranding of foods, drugs, and cosmetics.

Children's Bureau—$31,525,000

The Children's Bureau operating under the Social Security Administration makes this money available to states having programs for crippled children, maternal and child health and welfare services. The states are by law required to match these grants.

Bureau of Public Assistance (Medical and Health Payments)—Approximately $50,000,000.

This money will be used either for direct payments to physicians and hospitals and for medical supplies or to the beneficiaries themselves for payment for such services and supplies: (1) old age assistance, (2) blind, (3) needy permanently and totally disabled, and (4) dependent children. The bureau operates under the Social Security Administration. By law the states support approximately 40% of the total cost of these programs.

(Note.—The following 13 medical programs operate under the U. S. Public Health Service.)

Office of Surgeon General, Public Health Service—$2,900,000

This appropriation covers administrative expenses of the Office of the Surgeon General and the cost of the following programs: (1) evaluation of public health needs; (2) development and coordination of nursing resources; (3) international health activities wherein the U. S. P. H. S. acts for Department of State, Foreign Operations Administration, and other government agencies; and (4) general duty training.

Tuberculosis Control—$6,000,000

Grants to states providing diagnostic and treatment clinics, mass casefinding, and follow-up service total $4,275,000 of this appropriation. These grants must be matched by a minimum of one state dollar for each two federal dollars. The remainder of the appropriation finances direct activities of the Public Health Service for such programs as mass x-ray surveys, studies, demonstrations, drug evaluation, and BCG vaccinations.

Venereal Disease Control—$5,000,000

Grants to states having programs of venereal disease detection, treatment, and control amount to $1,976,500. A portion of this amount must be matched by a minimum of one state dollar for each two federal dollars. The federal government also furnishes technical assistance amounting to $2,268,500, mostly to pay federal employees assigned to state programs. The balance finances direct activities of the U. S. P. H. S. for mass examinations, drug evaluation, studies, and demonstrations.

General Assistance to States—$13,250,000

Grants to states must be matched on the basis of one state dollar for each two federal dollars.

Communicable Disease Control (Communicable Disease Center, Atlanta, Ga.)—*$5,000,000*

The Communicable Disease Center carries on programs of study in epidemiology, laboratory diagnostic services, and special projects in assistance to states.

Engineering, Sanitation, and Industrial Hygiene—$3,162,500

Five programs are supported by this appropriation: (1) water supply and water pollution control through several river basin offices that work with state and interstate agency officials, $903,500; (2) study of effects of radioactive substances on individuals, partially in cooperation with the Atomic Energy Commission, $275,000; (3) general sanitation, consultant services with states concerning milk and restaurant inspection, garbage disposal, food handling by interstate carriers, etc., $799,000; (4) consultation with states and studies of health hazards in manufacturing, mining, etc., $550,000; and (5) environmental research activities of Cincinnati office, $547,500. The balance is for administrative expenses.

Alaska—Disease and Sanitation Investigations and Control—$1,082,000

This appropriation will be divided equally between several grants to the territory and the financing of the Arctic Health Research Center at Anchorage.

Hospitals and Medical Care—$33,100,000

These funds are used for operational cost and maintenance of hospitals and health services in caring for American seamen, Coast Guard and Public Health Service personnel and their dependents, federal employees injured at work, leprosy patients, and narcotic addicts.

Foreign Quarantine Service—$2,900,000

This service operates about 250 quarantine stations on borders of the United States. It also operates about 25 medical examination stations on foreign soil for the examination of aliens seeking visas to enter the United States. Inspections are made of all seagoing vessels and aircraft entering the United States.

National Institutes of Health (total)—*$71,153,000*
  National Cancer Institute—$20,237,000
  Mental Health Institute—$12,095,000
  National Heart Institute—$15,168,000
  Dental Health Institute—$1,740,000
  Microbiological Institute—$5,738,000
  Institute For Neurological Diseases & Blindness—$4,500,000
  Institute of Arthritis & Metabolic Diseases—$7,000,000
  General Funds—$4,675,000

Hospital Construction Grants—Obligational Cash—$65,000,000

This appropriation will assist the financing of *new* construction under the Hill-Burton Act.

Grants for Hospital Construction — Liquidational Cash—$19,700,000

This appropriation is used to liquidate previously authorized construction now in various stages of completion.

Hospital Construction Administrative Expenses—$875,000

This appropriation is used for salaries and expenses of the hospital construction program at the federal level.

Veterans Administration—($747,415,264 Total)

Medical, Hospital and Domiciliary Administration—$7,757,900

This total covers expenses of administration of the Department of Medicine and Surgery in the central office and the six area medical offices.

Research—Approximately $5,500,000

The Veterans Administration conducts research by physicians and other scientists in such fields as radioactive medicine, with most of the work done in laboratories located within VA hospitals.

New Construction and Contract Liquidation—$38,685,664

Included in this figure is $21,185,664 to liquidate contracts for existing hospital construction so as to place this program on a pay-as-you-go basis. Another $17,500,000 is for planning and designing 1000-bed neuropsychiatric hospitals at San Francisco and Topeka, Kan., a 250-bed addition to the Houston VA hospital, and to start on construction of ancillary buildings at the three cities.

Supply Depot Operations—Approximately $1,350,000

Contract Hospitalization—$20,583,100

Non-VA hospitals, including federal, state, and private, at the end of the fiscal year were caring for 5,866 veterans on a contract basis. The largest single category was psychotic patients (3,084).

Domiciliary Care—$24,248,200

This total provides care for about 17,000 veterans who are incapacitated to the point of being unemployable but not in need of full hospital care. The agency operates 17 domiciliary facilities, 14 in conjunction with VA hospitals.

Outpatient Care—$92,677,900

Of this figure, about $7,000,000 is paid to physicians and $23,000,000 to dentists under the home-town care program. It calls for fees to doctors designated by local or state societies for services to veterans. The remaining $62,000,000 is for VA's outpatient care program in clinics.

Inpatient Care—$555,000,000

This covers inpatient care in 163 VA hospitals and provides an authorized 114,000 beds daily. Patients being treated for diseases or disabilities were as follows: 35.6% service-connected, 63.8% non-service-connected, and 0.6% nonveteran cases.

Medical Education and Training—$1,300,000

The VA operates training programs for physicians and other VA personnel in both the medical specialties and auxiliary services.

Capital Expansion—$312,500

This amount is available for expanding or altering about 100 VA clinics, mostly located in regional offices.

Department of Defense—($533,311,000 Total)

Army Medical Services—Approximately $238,994,000

This total is broken down by the Army as follows: About $84,000,000 for salaries of military personnel, including doctors in uniform; $76,975,000 for supplies and equipment; $62,530,000 for civilian personnel (salaries of physicians, dentists, nurses, technicians, etc.); and $15,489,000 for research, training, and other miscellaneous items.

Naval Medical Services—Approximately $161,429,000

The Navy's budget is broken down as follows: about $78,000,000 for salaries of military medical personnel; $36,529,000 for supplies and equipment; $28,730,000 for civilian medical personnel; and $18,170,000 for research, training, and other expenses.

Air Force Medical Services—Approximately $132,801,000

Total spending this year is divided about as follows: About $87,000,000 for salaries of military medical personnel; $18,874,000 for civilian medical personnel; and $26,927,000 for supplies, equipment, research, and other expenses.

Office of Assistant Secretary of Defense (Health and Medical)—Approximately $87,000

This figure covers salaries, travel, and administration for staff and consultant personnel.

Department of State—($14,127,733 Total)

World Health Organization—$2,993,400

The United States contribution for this year represents 33⅓% of WHO's total budget. Programmed spending of all available WHO funds, including those from the United States, is broken down as follows: Administration and salaries, 41%; advisory services to governments (consultants), 35.6%; contributions to regional offices for field programs, 13.6%; expenses of organization meetings, 3.8%; fact-gathering and administering international sanitary regulations, 3.8%; and expenses of expert committees studying various diseases, 2.2%.

Pan-American Sanitary Bureau—Approximately $1,320,000

The Pan-American Sanitary Bureau, the regional arm of WHO, has a budget for this calendar year of $2,031,800, of which the United States contributes 66%.

International Children's Emergency Fund—$9,814,333

The United States share of the Fund is about 60% of the total budget of about $16,000,000. The fund has allocated money for the current year as follows: Maternal and child welfare services and training, 37.8%; mass health programs to combat communicable diseases, 25.8%; child nutrition, including long-range feeding and milk conservation, 21.2%; and emergency feeding in disasters, 15.2%.

Department of Labor—($8,960,000 Total)

Bureau of Employees' Compensation—Approximately $8,500,000

This activity, covering specified federal employees and beneficiaries, corresponds to the Workmen's Compensation Agencies in the states. The total beneficiary coverage is currently estimated at 2,300,000. Benefits include payments of compensation for disability and death, the furnishing of medical and hospital services and supplies, treatment, and funeral and burial expenses.

Health and Safety Program—Approximately $460,000

The Bureau of Labor Standards within the Department of Labor has available $700,000 for its activities. From this total, about $400,000 will be spent for the promotion of industrial safety. An additional $60,000 will be used in programs for re-employment of the physically handicapped.

Foreign Operations Administration—($24,500,000 Total)

Technical Assistance Programs—$24,500,000

Money is given backward countries for training and demonstrations leading to setting up of national and local health services.

Department of Interior—($27,258,600 Total)

Bureau of Indian Affairs—$21,400,000

This money is used for operation of 59 Indian Bureau hospitals, sanitariums, and clinics; contract hospitalization; preventive and curative services, such as medical and dental field clinics; practical nurse training; and administration and salaries.

Bureau of Mines—$5,060,000

This money is spent for mine inspection and investigations, investigation of accidents and rescue work, and explosive testing and research.

Alaskan Mental Health Program—$798,600.

This item provides contract hospitalization in the United States for Alaskan whites and Indians judged insane.

Department of Commerce—($621,000 Total)

Bureau of Standards—Approximately $300,000

Tests are being made on such things as hearing aid batteries, substitutes for blood plasma, automatic blood pressure recorder, heart pump, and artificial kidney.

Civil Aeronautics Administration—$321,000

This item is for salaries and administrative expenses in carrying out the medical portion of the authority's flight safety program.

Department of Treasury—($2,790,000 Total)

Bureau of Narcotics—$2,790,000

The bureau's role is enforcement of the narcotic laws and the suppression of illegal traffic in drugs.

Department of Justice—($1,326,000 Total)

Bureau of Prisons—$1,326,000

This figure is for payments to Public Health Service for all medical and dental services for some 18,000 prisoners in 27 federal penal institutions.

Independent Offices—($68,019,600 Total)

National Science Foundation—$8,000,000

The foundation initiates and supports basic scientific research, evaluates research of governmental agencies, and correlates research programs of others. It awards scholarships and graduate fellowships in the sciences and fosters exchange of scientific information among scientists of the United States and foreign countries.

Federal Civil Defense Administration—Approximately $26,650,000

This money is divided into $22,500,000 for federal stockpiling; $3,900,000 for equal matching funds to states for stockpiling of medical items; and $250,000 for operations.

Atomic Energy Commission (Medical)—Approximately $26,565,000

This money will go for research and for vocational and special training, including fellowships.

Health Resources Advisory Committee—Approximately $91,000

This committee advises the director of the Office of Defense Mobilization on those health resource problems concerning medical manpower and blood.

National Advisory Committee to Selective Service—$265,000

This appropriation covers administration and salaries for committee headquarters and 51 state offices.

Panama Canal Zone (Medical)—$5,448,600

The Panama Canal Zone Government operates four hospitals, having a total capacity of approximately 1,400 beds. It also operates six outpatient medical clinics, two outpatient dental clinics, one school hygiene unit, a visiting nurse service, a quarantine service, a veterinary service, a sanitation and insect control program, and two large city health departments.

Federal Trade Commission (Medical)—Approximately $1,000,000

Miscellaneous—($7,000,000 Total)

Commission on Intergovernmental Relations—$500,000

This commission investigates all relationships between the federal government and state and local governmental units.

Commission on Organization of the Executive Branch of the Government—$500,000

This commission, under the chairmanship of Herbert Hoover, has until May 31, 1955, to complete a study of operations of the Executive Department, with a view toward effecting economies and promoting efficiency.

Federal Employees Health Programs—Approximately $6,000,000

The 79th Congress authorized the heads of federal agencies to provide health services designed to minimize illness and help United States employees to remain on the job. Clinics are established and maintained in federal agencies wherever there are large concentrations of employees.

ARMY

Dr. Bayne-Jones Receives "Super-Grade" in Army Medical Service.—Promotion ceremonies for Dr. Stanhope Bayne-Jones, technical director of research, Medical Research and Development Board, were held in the Office of the Surgeon General on Sept. 28. The promotion to grade GS-17 came as the result of a redistribution of the so-called super grade jobs from the Department of the Army. Dr. Bayne-Jones is the first to achieve a position of this high stature in the history of the Army Medical Service. As expert consultant to the chairman of the Army Medical Research and Development Board, he is responsible for insuring close coordination between the Army's medical research effort, similar programs sponsored by other federal agencies, and 115 cooperating civilian institutions.

During World War II, Dr. Bayne-Jones served in the Office of the Surgeon General as deputy chief of the preventive medicine service, director of the U. S. Typhus Commission and administrator of the Army Epidemiology Board. He was a brigadier general in the medical corps reserve, having been affiliated with the Army reserve program since 1915. After World War II and prior to his current assignment, he served as president of the joint administrative board of the New York Hospital-Cornell Medical Center in New York. In World War I, he served with both the British and the American armies, and after the war was the sanitary inspector for the Army of Occupation in Germany. Dr. Bayne-Jones has been awarded the Distinguished Service medal, Silver Star (two oak leaf clusters), the U. S. Typhus Commission medal, the Military Cross, Order of the British Empire, and the French Croix de Guerre, with bronze star.

Personal.—Capt. Joseph E. Molloy, of Chicago, has accepted a Regular Army commission in the Medical Corps at Brooke Army Medical Center, where he is on duty in the orthopedic service.

PUBLIC HEALTH SERVICE

Regular Corps Examination for Medical Officers.—A competitive examination for appointment of medical officers to the regular corps of the United States Public Health Service will be held on Feb. 2-4, 1954, at a number of points throughout the United States. Applications must be received no later than Dec. 24, 1953. The regular corps is a commissioned officer corps of members of various medical and scientific professions, appointed in appropriate categories, such as medicine, dentistry, nursing, engineering, and pharmacy. Appointments will be made in the grades of assistant surgeon and senior assistant surgeon. All commissioned officers are subject to change of station and assignment as necessitated by the needs of the service. Appointments are permanent and provide opportunities to qualified physicians for a career in clinical medicine, research, and public health.

The requirements for both appointments are United States citizenship, at least 21 years of age, and graduation from a recognized school of medicine. In addition, the assistant surgeon must have at least seven years of collegiate and professional training and appropriate experience, and the senior assistant surgeon must have at least 10 years of collegiate and professional training and appropriate experience.

Entrance pay for an assistant surgeon with dependents is $6,017 per annum; for senior assistant surgeon with dependents, $6,918. These figures include the $1,200 annual additional pay received by medical officers as well as subsistence and rental allowance. Provisions are made for promotion at regular intervals up to and including the grade of senior surgeon and for promotion by selection to the grade of medical director. Retirement pay after 30 years of service or at the age of 64 is three-fourths of annual basic pay at the time of retirement. Minimum disability retirement pay is ordinarily one-half of annual basic pay at the time of retirement. Additional information may be obtained from the chief, Division of Commissioned Officers, Public Health Service, Department of Health, Education, and Welfare, Washington 25, D. C.

FOREIGN LETTERS

CHILE

Isoniazid Treatment of Extrapulmonary Tuberculosis.—Drs. R. Anetto, G. Chaparro, and F. Velasco of Salvador Hospital in Valparaiso reported on isoniazid therapy of extrapulmonary tuberculosis in the *Aparato Respiratorio y tuberculosis.* They used an initial dose of 3 mg. of isoniazid per kilogram of body weight that was increased from 8 to 10 mg. per kilogram in treating patients with tuberculous meningitis. The patients were divided in the following groups: (1) 6 who received streptomycin (intramuscularly and intrathecally) with *p*-aminosalicylic acid and who, when relapses occurred, were given isoniazid alone; (2) 4 who were given streptomycin and isoniazid who had had no relapses; and (3) 11 in whom isoniazid was the only drug used.

Good results were characterized by (1) disappearance of headaches and anorexia within two weeks, (2) disappearance of the meningeal syndrome within three weeks, (3) gradual return of the spinal fluid to normal, (4) fall in the sedimentation rate paralleling the clinical improvement, (5) gain in weight, and (6) rapid subsidence of fever in comparison with that following the older treatments. Good results were obtained within from one and a half to five months in all of the patients with relapse, in three of the four patients treated with the combined therapy (the fourth patient died), and in two of the patients treated with isoniazid alone.

Dr. S. Del Rio and associates used isoniazid to treat 41 patients with tuberculous laryngitis and bronchitis. All 41 patients had pulmonary lesions, which were minimal in 1, moderate in 12, and advanced in 28. A total of 31 patients who were benefited by isoniazid had been previously treated with *p*-aminosalicylic acid and streptomycin without benefit. All the diagnoses were made by endoscopy, a second examination being performed 45 days after the beginning of the treatment and a third at its completion. The results of the treatment were evaluated 90 days after the initiation of therapy, and the patients' conditions were classified as improved, static, or worse. Improvement was noted in 36 of the patients, 18 of whom were judged to be completely cured. In three of the patients there were no changes and the condition of two became worse. Statistical analysis showed that the age and the sex distribution was not significantly different in the group treated with streptomycin and that treated with isoniazid. Thus, whereas isoniazid produced improvement in 36 (88%) of the patients, the therapy with *p*-aminosalicylic acid and streptomycin or streptomycin alone in a control series produced regression in only 66%. This difference was found to be statistically significant. Prior to the advent of streptomycin and *p*-aminosalicylic acid, only 25% showed improvement. The authors concluded that isoniazid not only gives a better result but that the improvement thus obtained occurs much faster.

Anniversary of Chilean Society of Dietetics.—The 10th annual meeting of the Chilean Society of Dietetics, Nutrition, and Toxicology was held recently in Santiago. A number of foreign delegates added to the importance of the occasion. Argentina was represented by Professor Cels, the United States by Prof. Phillip White, Cuba by Professor Lagomarsino, Brazil by Dr. Taveira, Uruguay by Dr. De Mello, and Peru by Professor Urguiete. Among the topics under discussion were "Protection of Foodstuffs," "Problems of Dietetics," "Presentation and Preparation of Food," and "Training of Personnel for the Science of Nutrition."

Fourth Sanitary Meeting Between Chile, Peru, and Bolivia.—The fourth meeting of the control committee of the Sanitary Convention of Chile, Peru, and Bolivia was held in Arica, Chile, on July 1 and 2. Its purpose was to appraise the results of activities during 1952 and to plan the program for the coming year. This meeting had a special importance this year, as it was found necessary to modify and amplify the agreement between these countries in the light of recent conceptions of international sanitation. In addition to the ministers of public health, the directors of the health service of the three countries (Chile, Dr. E. Suarez, Peru, Dr. L. Saenz, and Bolivia, Dr. J. Aramayo) were present. The points of agreement concerned intensification and amplification of the antimalarial campaign, establishment of a goal of vaccination of 80% of the population against smallpox, the control and treatment of venereal disease in the border regions, investigation of the prevalence of trypanosomiasis (Chagas' disease) and means of controlling its vectors, investigation of intestinal parasitic infestations and their treatment, adoption of the yellow fever control measures set forth in International Sanitary Regulation No. 2 of the World Health Organization, and the establishment of sanitary border posts between the three countries.

Hematological, Immunological, and Hemostatic Changes in Cirrhosis of the Liver.—Drs. C. Meza and H. Orrego reported on 82 patients with cirrhosis of the liver in *Revista Medica de Chile* for May, 1953. The cirrhosis was classified as serious or mild. The serious cases were those in which there was ascites, esophageal varices, lethargy, or coma. Of the 82 cases, 61 were considered serious. They found anemia in 61 of the patients (macrocytic in 36, normocytic in 21, and microcytic in 4). All of those with microcytic anemia had severe hemorrhages. The authors noted that the severe anemias were always associated with advanced cirrhosis but that some patients with advanced cirrhosis had a normal erythrocyte count. There was, however, a relation between the degree of anemia and the quantity of serum albumin. The leukocyte count varied between 2,000 and 45,000. In 40 patients the count was normal, in 27 there was leukocytosis, and in 15 there was leukopenia. Marked leukocytosis or leukopenia was associated with the serious cases of cirrhosis. Except in patients whose leukocytosis was due to infection or hemorrhage, a count of more than 20,000 white blood cells was found only in the patients in coma. In the neutrophils deviation to the left was frequently observed. Pathological granulations of the neutrophils were present in 51 of the patients. The absence of eosinophils was a bad prognostic sign. There was a correlation between the lymphopenia and the severity of the clinical findings. Autoagglutinins and isoagglutinins were studied in 18 patients, in 13 of whom the presence of agglutinins was detected. A decrease of the prothrombin activity of the plasma was found in all of the 15 patients in this part of the study, a decrease of the fibrinogen in 12, poor retraction of the clot in 8, prolonged bleeding time in 8, increased coagulation time in 7, and increased fibrinolytic activity of the plasma in 4.

COLOMBIA

Toxoplasmosis.—In March, 1953, Drs. A. Laverde L. and J. Arciniegas Castilla reported in *Anales de la Sociedad de Biologia de Bogotá* the second case of congenital toxoplasmosis observed in Colombia. The first case was reported in October, 1950, by Drs. M. Roca García, J. Camacho Gamba, and G. Esguerra Gómez. The subject of the present report is a child, 7 months of age, the second son of an American father and a Colombian mother. The child was born in Bogotá at full term and was apparently normal during the first few months of its life except for a tendency toward eczematoid dermatitis and diarrhea when given cow's milk. From the age of 6 months, he had strabismus of the left eye, which was accentuated with nearsightedness. A clinical examination showed that the right half of the cranium was smaller than the left half. The ophthalmoscopic examination showed, in

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

the left eye, an ovoid, macular plaque of chorioretinitis, of 2 papillary diameters. There was convergent strabismus of 25 degrees in the left side. Roentgenograms of the skull showed small calcifications. They were irregular and observable in the region of the frontal lobes and in the cerebellar region. The sphenoidal cleft of the left side was larger than that of the right side. The Sabin and Feldman reactions were positive for the mother (1:1,024) and for the child (1:4,096) and negative for the father. The infant is living and apparently is in good health.

Trypanosomiasis.—H. Ucros and C. Gerlein, on Sept. 5, 1952, before the Society of Biology of Colombia reported their observations on 128 reactions of deviation of the complement, which were made according to Kelser's technique for the American Trypanosoma. The authors obtained 91% positive results in animals that had been inoculated with a strain of T. cruzi and 100% negative results in the controls. The cultures prepared with material from the same animals showed 90% of positive results, which proves the value of making cultures with material of patients with trypanosomiasis (Chagas' disease). The reactions of 86 samples of human blood serums of patients with different diseases were as follows: positive in 65.7% of 35 patients with mucocutaneous leishmaniosis and positive in 82.6% of the cases of bucopharyngeal leishmaniosis and in 41% of the cases with only cutaneous lesions. In 35 samples of blood serums from 12 patients with malaria, 10 with syphilis, 8 with amebiasis and 5 with cancer, the reactions were negative in all cases. In 16 samples of blood serums of persons with various diseases, including three with a verified diagnosis of T. ariari, the reactions were negative in all cases, which shows the specificity of the test.

National Meeting of Obstetricians and Gynecologists.—The First National Meeting of Colombian Obstetricians and Gynecologists was held in Bogotá, Sept. 9 to 12, under the chairmanship of Dr. A. Aparicio Jaramillo. Drs. C. R. Silva Mojica and F. Tamayo were vice president and general secretary, respectively. Headquarters were at the Tequendama Hotel, and the surgical sessions were held in the San José Hospital. More than 240 specialists attended the meeting. The question of whether purely medical or purely obstetrical treatment was preferable for the toxicoses of pregnancy and the importance of prevention was discussed.

A paper on the Rh factor brought out the fact that the Rh factor should always be determined in women who are to receive blood transfusions, in order to establish the compatibility of the donor blood and to prevent the stimulation of anti-Rh substances in the patient's blood. In Rh-negative pregnant women who have an Rh-positive husband, the presence of anti-Rh agglutinins should always be determined so that emergency treatment can be made available in advance. A careful clinical and hematological examination should always be made on infants born to an Rh-negative mother, even if isoimmunization is not demonstrable in the mother. The practice of inducing premature delivery in Rh-negative mothers is no longer advocated.

Another paper told of the establishment of clinics for consultation on sterility in Bogotá, Medellín, and Bucaramanga. The number of these important clinics should be enlarged in many other gynecologic centers of the country. When married couples report for examination because of sterility, it was recommended that the first examinations should be made on the husband.

National Congress of Gastroenterology.—The Fifth National Congress of Gastroenterology was held in Cali City, Sept. 9 to 13, under the chairmanship of Dr. H. Anzola Cubedes. Drs. C. Camacho and J. Lega were vice presidents; W. Elasmar B, general secretary; and F. Rojas Turriago, treasurer. Headquarters were at the Aristi Hotel and the surgical sessions were held in the San Juan de Dios Hospital. More than 120 delegates were present. In addition to the presentation of many valuable papers, demonstration courses on endoscopy and radiology were given in the San Juan de Dios Hospital and the Clínica de Occidente.

ITALY

Progress in Treatment of Blood Diseases.—Professor Baserga read a paper on the treatment of blood diseases before the medicosurgical society of Verona on March 21, 1953. He asserted that anemia can and should always be cured, and he adhered to the classical distinction of hypochromic, hyperchromic, and normochromic anemia. In hypochromic anemia, determination of the amount of iron in the blood plays a great role in successful treatment.

Administration of iron to patients with hypochromic anemia should be based on the following fundamental points: 1. Intravenous administration of iron should be carried out only in patients in whom the diagnosis of hypochromic anemia is certain. 2. The total dose of iron to be administered should always be previously calculated. Iron administered orally is absorbed by the intestinal mucosa only if the patient lacks it, whereas the iron that is administered intravenously accumulates in the organs when the amount given is greater than what is needed to restore the hemoglobin level to normal. From this arises the danger of hemosiderosis when intravenous therapy is not indicated or when it is carried out improperly.

Discussing hyperchromic anemia, Professor Baserga said that today pernicious anemia is always cured with liver extracts and vitamin B_{12}. Cases have been reported in the literature in which there was sensitivity to folic acid and resistance to vitamin B_{12} or cases of sensitivity to liver and resistance to vitamin B_{12}, but they are rare. Therefore the therapeutic problem of pernicious anemia can be considered practically solved. On the other hand, the diagnostic problem is still difficult.

The use of tonic preparations containing vitamin B_{12} leads to the situation that almost all anemic patients are given large doses of the vitamin before an exact diagnosis is established. Because of this, the clinical and hematological picture of pernicious anemia is greatly altered and dissipated, while at the same time the neurological syndrome is not prevented. The physician should therefore learn to know the picture of disguised pernicious anemia. He should give great importance to the neurological examination because the most interesting clinical sign is the disappearance of the vibratory sensibility of the lower extremities.

Normochromic anemia is the most difficult to treat. Some authors say that it does not exist and that only in rare cases is hypochromic anemia due to lack of iron and deficient bone marrow function. However, in relation to the small amount of marrow present, the quantity of iron is sufficient. Often this is the complex picture seen in aplastic anemias that can develop into leukemia and agranulocytosis if the patient is kept alive by blood transfusions or other forms of treatment.

At this point Professor Baserga drew attention to the concept that he has supported for many years that in most cases of aplastic medullar reactions the following factors are present: an almost empty bone marrow, absence of peripheral anemia, and agranulocytosis. Often in the long run there is also aplastic anemia.

The question arises as to what therapeutic possibilities exist for this syndrome, which includes true aplastic myelosis, progressive myeloid atrophy, and aplasia caused by drugs. The speaker said that treatment of agranulocytosis consists mainly of repeated blood transfusions, and he spoke of the use of cortisone and corticotropin in hematology. He explained their mechanism of action, which is of an antibody and cytostatic nature and produces a general improvement that has not been well accounted for. The two hormones have mainly an antiallergic activity; this explains their pronounced therapeutic activity in all conditions that have some allergic aspects, such as agranulocytosis, acquired acute hemolytic jaundice, and acute thrombocytopenia.

Reviewing the literature on cortisone and corticotropin, he indicated the reasons that may make one product preferable to the other, the complications that may arise from their use in therapy, and the means to prevent or attenuate these dangers. He discussed treatment of hyperdysplastic diseases of the leukocyte, such as leukemia, lymphogranuloma, and lymphoblastoma. He explained the modern concepts about the pathogenesis of these conditions and listed the various aplasia-inducing agents like x-rays, radioactive phosphorus, arsenic, urethan, mustard gas, and corticotropin. Radiological therapy and careful symptomatic therapy have great importance in the treatment of chronic leukemia and lymphogranuloma.

Professor Baserga concluded that the treatment of anemia has already achieved its goal. In leukemic forms it is, however, only possible to prolong the life of the patient. Therefore the physician's first duty is to use all the therapeutic means that can improve the condition of the patient and prolong his life until science finds more effective remedies.

Convention on Tuberculosis.—The 33rd convention of the Swiss Association Against Tuberculosis was held in Zurich April 25, 1953. Many Italians participated. Professor Daddi, director, University of Milan Institute of Phthisiology, said that there may be in the same person streptomycin-resistant strains of bacilli in the tuberculous cavities while there are streptomycin-sensitive strains of bacilli in other areas of the organism. This was repeatedly proved in his clinic, and he is therefore convinced that therapy with this antibiotic should be continued even in those patients whose sputums contain strains of streptomycin-resistant bacilli. In fact, he obtained excellent results in many such patients.

Professor Baroni, director of the Sondalo sanatorium, reported the results of studies on isoniazid that are still in progress in the sanatorium laboratories. The capacity of the organism to break down and eliminate the drug varied among the various groups of patients. As a rule, the efficacy of the chemotherapeutic product is greater in the patients who break it down with lesser intensity.

Professor Garattini, from the University of Milan Institute of Pharmacology, advanced hypotheses that tend to reconcile the laboratory data, which contraindicate the combination of isoniazid with streptomycin and *p*-aminosalicylic acid, with the clinical data, which definitely favor such a combination. He discussed also the particular character of the resistance to isoniazid. Resistance to the drug is entirely specific. Therefore, new products that have marked structural analogies with isoniazid can be very active on isoniazid-resistant germs. This suggests new possibilities for the solution of the problem of tubercle bacilli resistance to the newest of the specific antibiotics.

Terminal Nerve Corpuscles in Walls of Arteries and Veins.—Professors Bertelli and Rugani discussed terminal nerve corpuscles of the vascular walls at a meeting of the Physiocritics Academy of Siena on April 29, 1953. Bertelli reported the results of studies made to establish the topography and morphology of the terminal nerve corpuscles situated in the wall of the popliteal artery and near it and to ascertain whether they are also present in the wall of the homonymous vein and near it. He performed serial microscopic sections of the popliteal vascular bundle that he had removed in all its extension and with much perivasal connective tissue from three men, aged 16, 40, and 56. He found that the corpuscles are rarely present in the adventitia of the popliteal vessels, their number being limited to one or two in the artery and vein of each person. There is a conspicuous number of them, however, in the lateral and medial angle where the popliteal vessels come in contact. There are other corpuscles in various points along the walls of the vessels, in contact with the adventitia as well as removed from the vessels, near the muscle bundles and the fibrous septa that from these proceed toward the adventitia of the two major popliteal vessels. He studied also the external form of the corpuscles and their complexity. These corpuscles belong to the category of specific and nonspecific corpuscles of Vater-Pacini. His studies are still in progress.

Professor Rugani discussed the terminal nerve corpuscles that are in contact with the walls of the femoral vessels and near them. He observed incapsulated nerve endings, mainly of the Vater-Pacini type, near the femoral vessels or in contact with them. The vessels had been removed from one side only in three men together with the surrounding adipose tissue, and many serial sections had been made. He gave exact information on the numerical topographic rate of the terminal nerve corpuscles with respect to the arterial and venous walls. He pointed out their interesting distribution in the common femoral artery and demonstrated the relation of some corpuscles with both the walls of the vessels and the arteriovenous anastomoses.

LONDON

Common Cold Virus.—After seven years' intensive investigation at the Medical Research Council's common cold research unit at Harvard Hospital, Salisbury, Dr. C. H. Andrewes and his staff have succeeded in propagating the common cold virus serially in cultures of embryonic human lung. In a preliminary communication in the *Lancet* (Sept. 12, 1953, page 546), they give details of their methods and their preliminary results. Cultures of human lung tissue were prepared from embryos up to 16 weeks of age. Five tissue explants were placed in each plasma-lined tube and 1 ml. of nutrient fluid was added. The nutrient material consisted of 90% bovine amniotic fluid (Seitz-filtered), 5% bovine embryo extract, and 5% normal horse serum. Penicillin, streptomycin, and phenol red were added to a final concentration of 100 units, 0.1 ml., and 0.002 mg., respectively. In later experiments, soy bean trypsin inhibitor was added to a concentration of 0.1 mg. per milliliter. The tubes were inoculated at 37 C in a drum revolving 14 times an hour. All cultures used for passage were at least three days old.

A series of passages was initiated by the inoculation of unfiltered nasal washings from a person with a typical afebrile cold. The material so obtained produced 13 colds in 130 volunteers, an incidence of 10%, where as parallel cultures not inoculated with infected material gave rise to no colds in 61 volunteers. Colds were produced by cultures up to and including the 10th serial culture; by that time the original virus had survived 35 days at 37 C and had undergone a 10^5 dilution. Culture materials were further diluted 1:5 before testing. There is thus "good evidence" that the infective agent has multiplied in culture. Dr. Andrewes sums up the position by stating: "Propagation of the common-cold virus in culture will give results of little practical value so long as growths of the virus can be proved only by tests on volunteers. We have every hope, however, that its presence will be demonstrated in other ways. Cytopathogenic effects on cultures have not yet been seen but most observations have hitherto been of roller-tube cultures with low-power objectives. There has not yet been time to apply to the problem various methods of microscopy and electron microscopy nor many available microbiological techniques. With demonstration of activity of the virus in cultures by any of these methods, study of the common cold would enter a new phase."

Field Work of a Diabetic Clinic.—"The need for field work in the care and aftercare of the diabetic patient becomes apparent the longer one works in a central clinic. It is doubtful whether the family doctor can find time to undertake all this work. Teaching the diabetic has to be slow, painstaking, and above all consistent. It is not always possible to have consistency in treatment with different schools of thought, neither of which are wrong but confusing to the patient. This work can be done by a woman of the right personality who must have considerable tact as well as expert knowledge. As she is based on the clinic, the patients recognise her as part of the authorised service and they do not consider her an intruder. Her reports to the clinic and to the patient's own doctor help to keep everyone informed of the situation. This work is better done by a specialist health visitor, as mistakes in management of the diabetic may readily occur where anyone lacks the experience which may be obtained only after working with the disease in all its vagaries." This is the opinion of Dr. Joan B. Walker, medical officer in charge of the diabetic department, Leicester Royal Infirmary, gained from experience in the County of Leicester that has a population of around 350,000 (*Lancet* 2:445, 1953). After consulting the local authority, hospital management committee, and the general practitioners' committee, a specialist health visitor for diabetic work was appointed. She attends the diabetic clinics and sees every new patient with the physician in charge. A full report is sent to the patient's physician, and arrangements are made by the health visitor for the district nurse to supervise the administration of insulin until the patient or a relative is capable of giving it unaided. During the first, second, or third day, the health visitor visits the patient with the district nurse, investigates the home conditions, and discusses any outstanding problems. A second visit is paid, after the patient has been to the clinic a second time, and the health visitor demonstrates how to test the urine and also checks the patient's diet and insulin dosage. On the third visit, the health visitor watches the patient test his own urine. Subsequent visits are made as required or at the request of the family physician or the clinic. Special attention is paid to the care of the feet in the elderly and those with peripheral vascular disease and to the assistance of patients with failing vision. The health visitor is able to give advice on such problems as provision of home helps, ambulance facilities, or applications for national assistance benefit.

Examples are given of the value of the work that such a health visitor performs. She is able to assist mothers in taking over the care of their diabetic children without any difficulty or unnecessary worry, and she visits schools attended by diabetic children so that she can explain hypoglycemia to the teachers and discuss the diet with the school cook. Most of the diabetic children take the school dinner without any modification. At the difficult stage of leaving school and beginning work, the health visitor can make sure that the person chooses suitable employment, visits the personnel manager, and discusses any dietetic problems with the canteen supervisor. Shift work is common in Leicester, and at one time it was considered advisable to keep diabetics from such work. This caused an inevitable detrimental effect on pay and promotion. With the aid of the health visitor, it has been possible to overcome this difficulty either by discussions with the employer or by advice given to the diabetic in how to adjust his diet and insulin intake to fit the shifts. Much useful work has been done in reducing the necessity for senile diabetics to visit the clinic and in supervising the tuberculous diabetic undergoing domiciliary treatment for tuberculosis. An interesting example is also quoted of how the health visitor can prove useful in an emergency. A batch of protamine zinc insulin was found to be faulty. On being notified, the manufacturers immediately recalled the whole batch, but in some rural areas the recall was difficult. At each home visit the health visitor checked the batch number of all the insulin vials in the house and found 29 patients who were using the faulty batch; 20 had experienced nocturnal thirst and polyuria, 18 loss of weight, 3 ketosis, 2 intercurrent infection, and 5 hypoglycemia. All responded immediately when given other insulin.

General Practitioner Research.—"Research Newsletter No. 1" of the College of General Practitioners (*The Practitioner*, Sept., 1953, page 307) reports that the college has established a research committee and opened a research register. The objects of the committee are "to assist general practitioners in work undertaken in their own practices, either single-handed or in study groups." In addition, help will be given, if requested, to existing research organizations in the collection of material. Although the most important part of this work of the college will be the encouragement of general practitioners to undertake research in those aspects of practice that interest them most, the college will also initiate investigations and form college research groups to work on other problems. No attempt will be made to compete with existing research organizations and work will not be initiated by the college that can be better done by others.

There are already many names of physicians on the research register of the college, and a directory has been prepared that contains the names and addresses of all members and associates on the register. With the name of each is entered the particular research interest expressed by him in his original application, and it is hoped that the directory will serve as a means of introducing physicians who have similar interests. "In this way, exchange of ideas and information may be effected, and study groups may be formed which can investigate problems of their own."

From an analysis of these entries "it is clear that there are three types of research-minded general practitioners." The first is the man who prefers to work alone and who may have a definite object in view, that is, an M. D. thesis. He may need advice on the value of his undertaking, on colleagues who are working on similar problems, and on the suitability of his work for publication. In all of these ways the college can help him, "It may put the 'one-line' worker who has exhausted all the clinical material in his practice in touch with a colleague who can provide him with more." The second type has interests in some wider field. When it is known that others share these interests, the next logical step is the formation of study groups within the membership of the register. The hope is expressed that "study-groups will form themselves in this way, introduced and helped by the College, but in no sense controlled by it." The third kind is willing to collect information to be analyzed by a central organization.

To advise it on all research problems the college has established a research advisory panel consisting of experts in a wide field of scientific and medical experience.

Smoke and Cancer.—In his presidential address to the chemical section of the British Medical Association, Prof. G. R. Clemo, director of the chemistry department, King's College, Newcastle-upon-Tyne, reported that analysis of smoke collected in Newcastle had revealed the presence of considerable amounts of a material that proved to be a derivative of pyrene and that gave highly characteristic derivatives resembling those of a well-known carcinogen. The possible relevance of this finding to the cause of cancer of the lung could not be ignored.

Aid to Antivivisectionists.—The curiously muddled thinking that characterizes many well-meaning members of the public on the subject of vivisection has once more come up. In an address to the zoological section of the British Medical Association, Dr. W. Lane-Petter, director of the Laboratory Animals Bureau of the Medical Research Council, drew attention to the fact that certain branches of research, teaching in particular, were seriously handicapped by the difficulty in obtaining sufficient numbers of dogs and cats. He pointed out that, if even a fraction of the dogs and cats that are destroyed annually were made available for research purposes, this problem would be solved. "If reputable public bodies were to assist the laboratories in this humane task the private dealer would go out of business, medical research would be the richer in time, money, and, above all, opportunity, and human and animal suffering would be substantially reduced." This admirably humane solution to a problem that is assuming increasingly serious proportions has produced an outburst from one of the "reputable public bodies" to which Dr. Lane-Petter referred, the Royal Society for the Prevention of Cruelty to Animals. Full justice can only be done by direct quotation: "On this matter of using stray dogs for experimental purposes, we can admit no compromise; and any attempt to alter the existing regulations which forbid such a practice, will be faced with resolute opposition by the R. S. P. C. A. We consider that the mere fact that a dog has become a stray means that he has suffered; and to change the law here, as has been done in the United States, would be a step of the most retrograde kind. Furthermore, the society could not break faith with the public who hand their dogs, cats, and other pets to us in order that we may give them a painless end."

Saccharin.—Having been informed by the Medical Research Council that certain artificial sweeteners are "undesirable for reasons of health," the Minister of Food has issued the Artificial Sweeteners in Food Orders, 1953, that prohibit the use of all artificial sweetening substances except saccharin in food.

CORRESPONDENCE

HYDROCORTISONE AND RESISTANCE OF TISSUE TO INJURY

To the Editor.—The Selye article that appeared in The Journal (**152**:1207 [July 25] 1953) is directed against the thesis that the glucocorticoids provide some "protective shield" around the tissues of the body. Experimental work is quoted from which a hypothesis, stating that "inflammation and necrosis are two related, but fundamentally opposed, types of reactions to nonspecific tissue injury," is derived. The key word in this hypothesis is "opposed." Temporally the two reactions are closely related; morphologically they may be separated. To place a teleological framework on the occurrence of necrosis and inflammation is to prolong the now defunct debate on the usefulness or harmfulness of inflammatory phenomena. It is necessary to recognize the importance of this class of recently defined hormones (cortisone and corticotropin) in general body reactions to injuries of various sorts. Partial insight as to how these hormones function on the local tissue level has been forthcoming in recent years (*Ann. N. Y. Acad. Sc.* 56:623, 1953). At the present time the greater part of the hormones' effect, on the local inflammatory reaction, seems to be in reduction and slowing up of inflammatory cellular and serum (?) phenomena. These hormones slow up the infiltration and reduce the number of inflammatory cells, particularly lymphocytes, allow for production of poor granulation tissue, and possibly reduce active antibody production. Their actual role then in local disease processes would seem to be in the nature of a controlling mechanism in these pathological tissue processes. The inhibition of inflammation would per se permit any sufficiently strong irritant to spread throughout the tissues and to produce necrosis. That subcutaneous or other tissues produce some granulation tissue and cellular barrier, even in the face of excessive hormones, is to be noted. Pathologists consider the importance of necrosis to cellular infiltration under the general heading of inflammation for discussion purposes. It is clearly understood that necrosis of portions of an organ may occur with little evidence of large amounts of inflammatory cell infiltration into the central portion of the necrotic site; an example is caseous necrosis of lymph nodes in various infectious diseases. Any necrosis of visibly measurable amount, however, if it exists within the body for a period of time, will produce cellular infiltration and circumscription. Indeed, the rule is necrosis to inflammatory cell exudate into the site. That the hormones under discussion have given us a slow motion picture of the forepart of this phenomenon, does not mean necessarily that the reactions occur separately. Has an experiment been devised that clearly proves that prolonged necrosis can occur without any inflammatory cell alterations?

The existence of other basic and important substances in necrosis and inflammation is generally recognized. Precisely how these interrelate with cortisone in the general phenomenon of inflammation has not yet been defined. That the importance of these local substances has been overemphasized and too many generalizations drawn from the limited experiments that first described them, is now generally conceded.

It is unfortunate that the article by Selye considers inflammation and necrosis as fundamentally opposed types of reactions. Necrosis, produced by whatever means, is but one in a long series of cellular changes that results in healing, provided the animal survives. The use of words such as phlogistic and antiphlogistic, while toxonomically sound enough, is to be deplored. Acceptance of the notion of the action of corticotropic hormones being a shield-like buffer against various irritants, while proposed at an earlier date, has by now been generally discarded.

An analysis of the article shows the following points. 1. Is the clinical assumption that glucocorticoid action is to provide a "protective shield" around the tissues of the body against pathogens correct? Answer: (*a*) Total lack of data to prove, in the area of those hormones greatest clinical usefulness, that pathogens are the responsible agent makes the protective shield notion unnecessary. (*b*) There is no experimental evidence for the existence of such a "barrier." 2. Is the statement that experiments are offered in evidence that these hormones can both protect and sensitize to injurious agents a sound one? Answer: (*a*) No evidence is offered for either sensitization, in the usual sense of the word, or hormonal protection, as such. 3. ". . . suppression of inflammation by glucocorticoids is virtually synonymous with the suppression of . . . disease phenomena. . . ." Answer: (*a*) Necrosis is increased, how can it be stated that disease phenomena are suppressed? 4. These experiments showed the production of a mild inflammatory response that protected the body against a subsequent severer injury. The severer (within limits) the primary injury the greater the protection. Answer: This general phenomenon and its modification by cortisone is generally recognized, it is not necessarily dependent entirely on cortisone for modification. 5. "It is not the inflammation that is 'necrotizing' but those histotoxic agents. . . ." Answer: This is not a clear statement, and in any case it does not consider local necrotizing agents produced by damaged tissues. 6. The histological pictures of cortisone-modified granulation tissue are similar to those produced by other workers.

It may be pointed out that the experimental work of Selye is similar to that of previous investigations. I do not take exception to the methods or techniques of the experiments but rather to the generalizations in the article. I take issue with certain terms, and it seems to me that the quantitative differences in tissue reactions produced experimentally are not sufficient grounds to call forth an attack on fundamental theses. An understanding of different enzyme and hormonal influences upon the phenomena of inflammation to necrosis to healing has progressed steadily during the last 100 years. The recorded work on cortisone effects in this area fit into the general pattern of previous tissue understanding.

TREATMENT FOR VARICOSE VEINS

To the Editor:—A recent paper by Biegeleisen in the April 15, 1953, issue of the *New York State Journal of Medicine* describes that author's experience in the treatment of varicose veins. This report was abstracted in the Aug. 15, 1953, issue of The Journal. The author states that "in the absence of proved permanency of cure by surgical means, injection treatment remains the treatment of choice in most cases." This statement is in direct conflict with the reports from leading medical centers throughout the country and, therefore, deserves careful analysis.

Recent experimental and clinical investigations have demonstrated that injection therapy is not an effective method of treatment for varicose veins. It is impossible to localize accurately the effects of a sclerosing solution. Even in expert hands, injections may produce allergic reactions, skin sloughs, and deep phlebitis. Kinmonth and Boyd state that histological studies of veins injected with sclerosants indicate that valves may be damaged by doses that are too small to even produce obliteration of the vein. Hanschell feels that varicose veins thrombosed apparently solidly by sclerosants seldom fail to be recanalized completely: "If injected veins with or without concurrent ligation had been followed for periods over 10 months, injections would long ago have been abandoned as useless." Prioleau states that injections should be reserved only for the obliteration of small unsightly varicosities. Garber also concludes that the benefit, if any, derived from sclerosant solutions is at best of a temporary nature.

The ideal method of treatment for varicose veins should include the following features: (1) Elimination of all venous incompetency at its source by ligation of all varices at their junction with the deep veins; (2) extirpation of the remaining varicose vein segments so that few, if any, postoperative injections are necessary; (3) making of few incisions so that the operating time is short and the cosmetic result good, and (4) local anesthesia and mobilization of patient almost immediately postoperatively. These criteria are best met by a proper high ligation of the long saphenous vein, followed immediately by a complete stripping procedure. Total removal of the diseased saphenous system can be performed with local anesthesia on a semiambulatory basis. Postoperative treatments are reduced to a minimum since few, if any, injections are necessary. Not only all incompetent veins are localized preoperatively and effectively eliminated at operation but, by stripping out the saphenous vein, all other communicating branches are cut off and the possibility of incompetency developing at these sites at a future date is minimized. Many patients who have had both operation and injections stated the injections caused more pain and disability than the operation.

Dr. Biegeleisen, in comparing sclerotherapy with surgical treatment, compares his series of patients treated with injections with "62 cases undergoing various types of venosurgery. They included the author's private patients as well as others." Fifty-eight of these 62 patients had high ligations or multiple ligations. On the basis of this group of patients, the author describes a very high incidence of recurrence of varicose veins and of lymphedema following operation. In the first place, a stripping procedure was used in only two patients, and this operation is now generally accepted as the most effective surgical treatment for varicose veins. Second, the operations were performed by several physicians, and their exact technique is not described. Unfortunately, in a significant proportion of cases, the long saphenous vein ligation is not performed high enough (flush with the femoral), and the small branches, which persist, pave the way for the recurrence of varicosities. As far as the incidence of lymphedema is concerned, in a series of 3,300 cases operated upon by Linton, Silbert, Bull, and myself, not one instance of "lymph-leg" has been noted during the past 15 years. This contrasts sharply with the results reported by Biegeleisen. If all active infection in the extremity has been controlled and if the surgeon avoids any enlarged lymph nodes or lymphatic vessels that may be present, there should be no postoperative lymphedema.

The ideal treatment for varicose veins consists of the eradication of all detectable venous insufficiency in the most rapid manner possible, with the least time loss, discomfort, and expense for the patient. Injection treatment is a palliative, not a definitive, method of treatment, and it does not accomplish this objective. After analyzing the literature, communicating with other specialists, and evaluating my own results, it is apparent that this objective is best achieved if a careful high ligation and complete stripping procedure is performed.

HANSENOSIS FOR LEPROSY

To the Editor:—Recently I received a letter from Mr. Stanley Stein regarding the acceptability of the name Hansen's disease to supplant the word leprosy. Mr. Stein is editor of *The Star*, a magazine published by patients of the U. S. Public Health Service Hospital, Carville, La. I share in the general objection to the use of eponyms in designating diseases. However, I believe a less opprobrious term than leprosy is desirable providing it has taxonomic acceptance.

As is well known, the micro-organism generally accepted as the causative agent of leprosy is an acid-alcohol-fast organism discovered by Hansen, a Norwegian physician, in 1868. The biological characteristics of this organism require its classification under the family Mycobacteriaceae, where it is correctly placed under the genus Mycobacterium (Breed, R. S.; Murray, E. G. D., and Hitchens, A. P.: Bergey's Manual of Determinative Bacteriology, ed. 6, Baltimore, Williams & Wilkins Company, 1948, pp. 876-891). To this, there can be no rational objection. The objectionable feature, and the obstacle that must be surmounted in considering a change in nomenclature, is the name of the species, which is leprae. As a way around this difficulty, the name of the species might be changed from leprae to hansenii (in honor of Hansen who discovered the organism). The name of the organism, then, might become officially Mycobacterium hansenii. The disease produced by this organism could then properly be designated hansenosis. This would, I believe, be correct in a taxonomic sense and would meet the objections of those who, for eponymic reasons, dislike the name Hansen's disease.

I do not consider what is written here to be authoritative. I am not a bacteriologist and probably should not encroach on the field of those who are. My views are given as suggestions and probably have occurred to others. They are offered in further exploration of a problem that is of concern to many persons. Those who seek more information regarding the origin of the term leprosy may consult the article by Lendrum (*Am. J. Trop. Med.* [Nov.] 1952), who considers the word leprosy a barrier to sound medical care and a historical misnomer.

Mayo Foundation, Rochester, Minn.

STAIN FOR LIPID BODIES

To the Editor:—The article "Stain for Lipid Bodies in Urinary Sediment" (*J. A. M. A.* **152**:1713 [Aug. 29] 1953) leaves with the reader the definite impression that (*a*) the staining of urinary sediments, although until recently not widely utilized, is now being widely utilized and (*b*) that the authors have proposed a new method for staining urinary sediments in order to reveal lipid bodies. It would be difficult indeed to know how widely staining methods for urinary sediments are employed, but it is likely that such methods are seldom used even today. The reference to this matter cited is by no means the only one, for there have been many, including one by Behre and Muhlberg (*J. Lab. & Clin. Med.* **22**:853, 1937). The reason staining methods are not widely employed is that experienced observers do not find them necessary or advantageous except under unusual conditions. With regard to the method of staining sediments with Sudan 3, which the authors give in detail, this method is one of the oldest, and there is nothing new about the method proposed by the authors.

PHYSICAL ROLE OF PLATELETS

To the Editor:—Between the covers of THE JOURNAL two references to hemostatic mechanisms have recently appeared (Transfusion of Platelets, editorial [Aug. 8] p. 1434, and Pfizer's Spectrum [Aug. 29] adv. p. 28). Both of these omit the mechanical role of the blood platelets in arresting hemorrhage. This fundamental role of the platelets is frequently overlooked by chemists studying coagulation, but I do not understand how it can be consistently overlooked by physicians and physiologists with a comprehensive point of view.

Independent observation by Hayem and by Bizzozero in the 1880's established that blood platelets clump together and fill in the gaps in cut blood vessel walls. Apitz, Zucker, and Hugues have made direct observations of this process in mammals in recent years, and my study of biopsy material showed that man is like other mammals in this respect. When a muscular vessel is opened, a sizeable platelet mass forms at the site of injury within two minutes. As this plug forms, it is, at first, leaky and rivulets of blood can be seen spurting through it; possibly the fibrin mechanism is responsible for making this platelet seal waterproof (bloodproof). In some instances the platelet plug may be washed away several times, by the force of the bleeding, before it finally becomes fixed. One might suppose that fibrin is involved in this fixing too. In any case, the long-observed fact is that platelets, not fibrin needles, are the normal sealers of muscular blood vessels. The fact that platelets also contain and release chemical factors involved in hemostasis and clotting is not debated. That fact should not blind us to the platelets' basic role as morphological entities.

COUNCIL ON MEDICAL SERVICE

SUMMARY OF A STUDY OF MULTIPLE SCREENING

The Council on Medical Service has completed a study of 22 multiphasic screening programs carried on in various parts of the United States. The study report is being published in lithographed form for those particularly interested in multiple screening. The following paragraphs contain a summary of the study report. No effort has been made to evaluate these programs at this time; rather the Council has tried to report the opinions and ideas of physicians familiar with multiple screening and let the readers make their own decisions.—Ed.

The Council on Medical Service has investigated the subject of multiple (multiphasic) screening and has published this study for distribution to those interested in the subject. Because the subject is controversial, because it has some ardent advocates, and because it has equally ardent opponents, the Council desired to explore the subject in as objective a manner as possible, to present what facts are available, and to show all points of view. The Council has obtained its information through reports from the literature, material on file at the Council's office, and direct communication with persons and agencies responsible for the administration of the various multiple screening programs.

Following is a brief résumé of the complete report, which summarizes some of the pertinent data contained in the 22 multiple screening surveys included in the study. Several surveys were not included in the report. Results of some are not ready for publication owing to data not yet collected or coded and inability or delay in obtaining approval for publication. However, the included 22 surveys are a representative sample of multiple screening. They range in number of persons screened from 500 to 500,000 and in types of persons covered from insurance company employees and small industrial plant workers to city and statewide screening surveys of the general public.

MULTIPLE SCREENING DEFINED

During the last five years many multiple screening surveys have been conducted. Much has also been written both for and against such surveys, and some varying concepts have been expressed. Therefore, a definition is needed that embraces the fundamental concept and expresses the consensus of those actively engaged in the administration of multiple screening surveys. The basic definitions agreed upon at the National Conference on Chronic Diseases: Preventive Aspects, held in Chicago March 12 to 14, 1951, led to the following formulation. This definition is consistent with the concept of multiple screening as expressed in the surveys studied. Multiple (multiphasic) screening is the use of two or more simple laboratory tests, examinations, or procedures, applied rapidly and on a mass basis, to determine presumptive evidence of unrecognized or incipient disease or defect. It has been repeatedly emphasized that screening should in no way be confused with diagnosis. It is merely a step toward diagnosis and a method, however imperfect, for determining the persons most needing referral to their physicians for further study, diagnosis, and treatment. By this method large numbers of apparently well persons can be tested and examined by the use of simple laboratory tests or procedures administered for the most part by nonprofessional personnel and checked by physicians. Persons with positive results are then referred to their family doctor.

OBJECTIVES

The objective in nine surveys was health education and a desire to seek out hidden, specific disease in the population screened. Seven sought mainly to evaluate the potentiality of multiple screening and to test the principles involved. Three surveys were primarily interested in an employee health service coverage, and three others sought to accomplish an economy of administration and operation and give better service to the persons screened than would be possible through a single disease casefinding program.

APPROVAL AND SPONSORING AGENCY

Fifteen surveys were officially approved by medical societies, local and/or state, depending on the area covered. In addition, one had indirect medical society approval while another was approved by the physicians of the area concerned. Four of the screening programs were not submitted for medical society approval because the tests were not available to the general public but rather were confined to a particular employee group, one of which was covered by a union health service plan. Almost all of the multiple screening programs that were open to the public were conducted by the state, county, or city health departments with active cooperation from other health agencies, including active participation in six instances by the local medical society.

CLINIC FACILITIES AND OTHER DETAILS

The screening clinics in many instances were set up with a mobile chest x-ray trailer as a basic component; in other instances the facilities of regular clinics were used in off hours; and in others temporary clinics were assembled at schools, stores, churches, vacant rooms at industrial plants, and booths at fairs. The time per person screened varied from 3 minutes to 60 minutes, depending on the number of procedures performed, which ranged from 2 to 15. Those procedures included a chest roentgenogram, serologic test for syphilis, determination of hemoglobin level, determination of the blood sugar level, and determination of the erythrocyte sedimentation rate; measurement of the sugar and albumin content of the urine, blood pressure determination, electrocardiogram, measurement of the height and weight, tests to determine sight and hearing defects, Papanicolaou smear test, hematest (for occult blood in feces), self-screener history, and a physical examination or parts thereof. The examining units staff consisted of a supervisor; various numbers of technicians, nurses, clerks and volunteer workers; and one or more physicians on duty continuously, alternately, or just part-time.

FINANCING AND COST

Sixteen surveys were financed by money and contributed services of the state departments of health, county and/or city health departments, local medical societies, local chapters of the tuberculosis and cancer associations, and other community health agencies. Seven of those 16 were also aided by grants, services, and/or equipment from the United States Public Health service. In three surveys the employer paid the total cost of screening. One was financed by a union and employer health and welfare fund, one by a health service plan with the aid of local health agencies, and one with the patient himself paying part of the cost, the remainder being absorbed by the medical school clinic and other health agencies. The cost per person screened in the 22 surveys (exclusive of follow-ups) ranged from $1.03 to $15.00 per person.

RESULTS

Ten of the 22 surveys were chosen for a table in this review because they provide the most complete data available concerning both results of screening and results of medical follow-ups. That data may be of some value in evaluating the results of multiple screening as it has been applied in actual practice. The table in itself, of course, does not tell the complete story. Several interesting observations and facts concerning those results will serve to indicate more clearly the significance of the figures thereon.

By way of further explanation regarding the table, it should be noted that data contained in the complete report show that 28% of the positive screenees in survey number 4 did not respond to medical follow-up and of the 72% who did respond almost 50% had confirmed diagnoses of serious disease after medical follow-up. In addition, 75% of the confirmed diagnoses were for cardiovascular disease and diabetes, and a pronounced correlation with obesity was observed (43% of the screenees were 20% or more above ideal weight and 10% were over 40% above ideal weight). Of interest, too, in this survey is the discovery that only 19% of those with subsequently confirmed diagnoses were then under a physician's care.

In survey number 14 nearly all of the 583 screenees had one or more positive test results; all were adults over 45 years. In this survey those with positive test results were examined further to the point of diagnosis and then referred to their family physician for follow-up and treatment. Cardiovascular disease and diabetes constituted 75% of the confirmed diagnoses of serious disease.

Informative replies were received from physicians in 69% of the referred cases in survey number 15. As noted in the table, 1,646, or 63%, of the screenees had positive findings on screening. It was estimated that only about 3% of those referred for a condition did not visit their family physician. In surveys 16 and 17 informative replies from physicians were received on only 50% of the positive screenees who were referred to their physicians for further study, diagnosis, and treatment, while 76% of the referred cases were reported on by personal physicians in survey number 18. When the data were broken down according to disease finally diagnosed and confirmed, it was found that the family physician confirmed the screening test findings in a ratio of one to two in the following conditions: anemia, heart disease, hypertension, diabetes, respiratory tract infection, tuberculosis, and syphilis. In surveys 18 and 19 cardiovascular disease alone accounted for 75% of the confirmed diagnoses of serious disease after follow-up.

Additional data from that given in the table on survey number 22 indicate that the follow-up or report of follow-up for the various conditions screened was made on from 50 to 80% of the persons referred to their physicians. Persons with confirmed diagnoses of serious disease made up approximately 50% of those coming to follow-up and/or of those coming to follow-up and reported on by their physicians.

Results of Multiple Screening Surveys

Survey *	No. of Persons Screened	No. of Procedures Used	No. of Persons With One or More Positive Test Results	No. of Persons With Serious Disease Diagnosed After Medical Follow-Up †	
				Actual Number	Number/ 1000
1	651	9	352	135	207
2	470,379	3	Data not available	21,964	44
3	945	6	174 ‡	36	38
4	3,994	12	2,521	848	213
14	583	14 plus	1,605 ‡	141	241
15	2,620	15 plus	1,646	186	71
16	4,536 §	15 plus	2,815	360	79
17	1,172	13 plus	704	234	200
18	1,004	13 plus	671	218	217
22	37,609	9	13,113	2,622	69

* The surveys are numbered according to the alphabetical arrangement by state in complete report.

† Excluding vision, hearing, and weight abnormalities.

‡ Number of positive test results.

§ Number tabulated from total of 5,057 screened.

SUMMARY ON RESULTS

In summary, then, it is found that the incidence of lack of response to follow-up on the screenee's part ranged from 1% to 50%. Reports on referrals by physicians making diagnoses after medical follow-up were made in from 50% to 80% of cases, and the incidence of confirmed diagnoses of serious disease after medical follow-up was as high as 50% in several surveys.

It seems significant, therefore, as shown in the column to the right in the table, that the actual number of diagnoses after follow-up of serious disease made and confirmed per 1,000 persons screened ranged from 38 to 241. On the basis of surveys in which a differentiation was made, it may well be assumed that the average yield in previously unknown cases was better than 50%.

COMPARISON WITH SINGLE DISEASE CASEFINDING SURVEYS

The final results, after medical follow-up of the multiple screening surveys in new cases of tuberculosis and diabetes found, compare favorably with the results of special casefinding surveys involving those particular diseases. It is apparent, therefore, that the multiple screening programs did not decrease the effectiveness of tuberculosis and diabetes casefinding.

OBJECTIONS

Many objections have been voiced against the use of multiple screening. Some are valid dangers and must be cautioned against, but others seem to be based upon misconception. As it is not the purpose of this report to defend or refute these objections, they shall be listed and judgment as to their validity shall remain with the reader.

1. A medical production line type of examination by machine cannot exclude or detect all incipient disease.
2. Multiple screening could put the physician backstage in the diagnosis of disease.
3. It may engender into the minds of those in whom abnormalities were not found a false sense of security.
4. It may cause undue apprehension and expense for those who are found to have false positive results from screening tests.
5. Multiple screening represents inadequate medical care and as planned and practiced is based on untenable premises.
6. The diagnostic techniques in multiple screening that have been devised as a means to an end are used as an end in themselves.
7. The physician has no opportunity to secure an intimate knowledge of the patient.
8. There is no opportunity for an appraisal of the "negative" group by a physician.
9. Most of the tests that are employed do not possess even an approximately precise value or measure that, on the one hand, may indicate that a finding is within physiological limits, or, on the other hand, is really indicative of a disease process.
10. Multiple screening is an infringement on private practice; it is the "Trojan horse" of socialized medicine.
11. In multiple screening there is need for a tremendous amount of community organization in order to maintain public interest and enthusiasm.
12. Multiple screening programs consume a great deal of the time of key personnel of the health department and cooperating voluntary health agencies.

ADVANTAGES

The stated advantages and comments favorable to multiple screening were not listed categorically in the complete report because they were expressed in the descriptive data of the surveys. However, in an abstract such as this, it becomes necessary to reproduce a listing of some of the most prevalent comments favorable to multiple screening as well as the list of objections.

1. Multiple screening is an excellent preliminary procedure to any form of examination by reducing the cost and time factors, thereby making it possible to extend periodic examinations to significantly larger groups of the population.
2. Screening programs are one of the practical ways of bringing the benefits of early detection to as many persons as possible. They can help sort out persons who are apparently well but who in reality may need medical care.
3. Multiple screening has been demonstrated to be an effective method of health education and its public relations value has great merit.
4. The multiple screening program was an aid to making people health conscious and seemed to stimulate the desire for regular check-ups.
5. Pooling of results of mass survey studies give invaluable information concerning incidence and prevalence of disease in the population.
6. Multiple screening examinations are flexible. They can be adapted or modified to fit specific groups under consideration and resources that are locally available.
7. As a program of prevention, multiple screening has caused a large number of apparently well persons who were not aware that they might have a progressive disease to consult their physician.
8. Multiple screening is an attempt by the medical profession to make more adequate medical care available to more persons through their family physician.
9. Multiple screening clinics are an effective weapon against the proponents of socialized medicine. The program can be controlled by the local medical society.
10. The patient is enabled, through multiple screening, to benefit in a single visit to his physician from the most recent developments in preventive medicine and health supervision.
11. Multiple screening for chronic diseases presents the possibility for a more economic and more productive use of personnel and facilities than is possible with multiple independent casefinding efforts.

MEDICAL MOTION PICTURES

The Treatment of Mental Illness by Topectomy: 16 mm., color, sound, showing time 25 minutes. Produced in 1951 by, and procurable on loan from, New York State Department of Mental Hygiene, Albany, New York.

Some years ago a special project in the treatment of mental diseases was undertaken in New York. This was quite an elaborate project in which the patients were studied, in most cases, by a battery of psychiatrists before and after an objective procedure was carried out. The study is still in progress and the patients operated on four years ago are still under close psychiatric scrutiny. This had involved a great deal of time and a great deal of money. This report-type film concerns the objective procedure that was carried out on these cases. This was also subject to very careful specifications. It involves the removal of a certain amount of cerebral cortex from both sides of a certain part of the brain. The utmost care has to be taken with regard to the location of the surgical extirpation and its extent. This procedure was given the name of topectomy. As it is carried out at only one place under these carefully controlled circumstances, it was thought that it might be of interest to persons at a distance to know just what the objective procedure involved. Psychiatrists who might contemplate such a procedure for a patient might be especially interested in seeing the surgical procedure.

The film appears, by its language and its introduction, to be aimed at a mixed commission of laymen, physicians, and public officials who are supporting the venture. The language is extremely simple and, as far as the medical profession is concerned, redundant. Nevertheless, the surgical procedure can be seen and understood by anyone who happens to be interested. It is not suggested that this be shown to unsuspecting laymen, but rather to especially interested persons and particularly psychiatrists. The photography is satisfactory.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Vitamins: Sale in Food Stores.—The plaintiff, a retail grocer, filed suit to obtain a declaratory judgment determining the proper construction to be placed on the Minnesota Pharmacy Act insofar as it affected the plaintiff's right to sell, at retail, tablets, capsules, or liquids containing vitamins in their original packages as prepared by the manufacturer or distributor, without giving any directions as to their use except such as are given on or in the package in which they are offered for sale. From an adverse judgment the plaintiff appealed to the Supreme Court of Minnesota.

Portions of the Minnesota statute involved in this action are as follows:

"Section 151.15. It shall be unlawful for any person to compound, dispense, vend, or sell at retail, drugs, medicines, chemicals, or poisons in any place other than a pharmacy, except as provided in this chapter. . . .

"Section 151.01 Subdivision 1 . . .

"Subdivision 5. The term 'drug' means all medicinal substances and preparations recognized by the United States pharmacopoeia and national formulary, or any revision thereof, and all substances and preparations intended for external and internal use in the cure, mitigation, treatment, or prevention of disease in man or other animal, and all substances and preparations, other than food, intended to affect the structure or any function of the body of man or other animal.

"Subdivision 6. The term 'medicine' means any remedial agent that has the property of curing, preventing, treating, or mitigating diseases, or that is used for that purpose.

"Section 151.26 . . . nothing in this chapter shall prevent the sale of common household preparations and other drugs, chemicals, and poisons sold exclusively for use for non-medicinal purposes.

"Nothing in this chapter shall apply to or interfere with the manufacture, wholesaling, vending, or retailing of non-habit forming harmless proprietary medicines when labeled in accordance with the requirements of the state or federal food and drug act; nor to the manufacture, wholesaling, vending, or retailing of flavoring extracts, toilet articles, cosmetics, perfumes, spices, and other commonly used household articles of a chemical nature, for use for non-medicinal purposes."

The plaintiff was not registered as a pharmacist or assistant pharmacist, and he did not, in the operation of his food store, employ a phamacist or assistant pharmacist. Each of the boxes, vials, or containers in which the tablets or capsules were offered for sale contains the information required under the Federal Food, Drug, and Cosmetic Act and the regulations issued thereunder and under the laws of the state of Minnesota.

The Minnesota statutory definition of the term "drug" breaks down into three parts or categories, namely, (*a*) medicinal substances and preparations recognized by the United States Pharmacopoeia and National Formulary or any revision thereof; (*b*) substances and preparations intended for external and internal use in the cure, mitigation, treatment, or prevention of disease in man or other animal; and (*c*) substances and preparations, other than food, intended to affect the structure or any function of the body of man or other animal.

The defendants, members of the state board of pharmacy, contended that the products the plaintiff sought to offer for sale are drugs and that they may be sold only in a pharmacy under the personal supervision of a pharmacist or assistant pharmacist.

The plaintiff contended first that the vitamin products that he proposed to sell in his food store constitute food or food products and are not drugs within the meaning of the Minnesota statute. All of the exhibits offered by the plaintiff, the Supreme Court said, contained some of the vitamins recognized by the United States Pharmacopoeia, and most of them contained several of such vitamins in various amounts and combinations. We are convinced, said the court, that the products that the plaintiff wishes to offer for sale come within the first category of the statutory definition of a drug. It is noticeable, the court continued, that the phrase "substances and preparations," as used in the statutory definition of a "drug" given in paragraph (*a*), is qualified by the word "medicinal"; therefore, only those substances or preparations used for medicinal purposes and recognized by the United States Pharmacopoeia are classified as drugs. That vitamins are used internally for the cure, mitigation, treatment, or prevention of disease in man cannot well be subject to serious doubt. Even plaintiff's experts agreed that a vitamin deficiency is or may be a disease and that when vitamins are prescribed for the treatment of such disease they are prescribed as a drug. The evidence sufficiently sustains the finding that the preparations under consideration come within the classification of subdivision (*b*). There is no dispute that vitamins are a part of much of the food necessary to maintain life and permit growth. The question raised by subdivision (*c*) is whether, since vitamins are component parts of food affecting the structure or function of the body of man, they may still be a drug when used to affect the structure or function of the body of man in a way that ordinarily is not true of food. The true test is: Can the preparations now under consideration affect the structure or function of the body of man or other animal in a way not ordinarily affected by the consumption of food? As so tested, said the court, we hold that the preparations again fall within the statutory requirements. These preparations not only are capable of use as food supplements, but may be used for other purposes consistent with the statutory requirement that they affect the structure and function of the body of man in a manner not affected by foods. The opinion of many eminent specialists in the field of medicine and chemistry called by defendants was that the vitamin products, involved are drugs. We conclude, said the Supreme Court, that they meet all the requirements of a drug set forth in the Minnesota statute.

The plaintiff next contended that, even if such products are drugs, they are exempt from the operation of the pharmacy act by reason of the fact that they are common household preparations and are sold exclusively for use for nonmedicinal purposes. The mere fact, said the court, that the products are harmless household remedies does not except the sale of the products from the operation of the statute unless they are also sold exclusively for nonmedicinal purposes. It is clear that the sale of the products here involved is not so limited. The evidence amply sustains the court's findings that they are not sold exclusively for nonmedicinal purposes; as a consequence, they do not come within this exception of the statute.

The plaintiff next contended that the drugs are exempt from the operation of the pharmacy statute by reason of the fact that they are not habit-forming and are harmless proprietary medicines. The evidence will not sustain the plaintiff's contention that all vitamins are harmless. But, even if we hold that the preparations are harmless if taken as directed, said the court, they are not proprietary medicines. While it is difficult to define proprietary medicines exactly, it is much less difficult to determine those preparations that are not proprietary medicines, and that is as far as we need go. Obviously, before a medicine can be classified as a "proprietary" medicine it must be implied that it has been compounded by a manufacturer who prepared the medicine according to some formula of his own. It does not follow that all drugs or medicines compounded by a manufacturer and sold in the original container under the name of the owner who prepared the substance are proprietary medicines. The products now under consideration are simply natural or synthetic vitamins of various kinds and combinations carried or contained in a neutral excipient. Any manufacturer having the requisite skill and equipment could prepare any one of the preparations involved or one of a very similar nature. Under these circumstances, it cannot be said that the product is a proprietary medicine.

Finally, the plaintiff contended that, if the Minneseota pharmacy act restricts to pharmacists the sale of vitamin products offered for sale as dietary supplements, the statute is unconstitutional. The Minnesota constitution provides "No person shall . . . be deprived of . . . property without due process of law." It also provides ". . . The legislature shall pass no local or special law . . . granting to any corporation, association or individual any special or exclusive privilege, immunity or franchise whatever, . . ." The constitutionality of our pharmacy act, said the Supreme Court, has been before this court in several cases and has been sustained in all of them. The act should be sustained if it has a reasonable tendency to protect the public health or welfare. There are many kinds of vitamins, all of which are intended to be taken for different purposes and deficiencies and for alleviation of different physical disabilities. Some are undoubtedly taken to prevent vitamin deficiencies and the physical disabilities that result therefrom. A pharmacist not only is in a better position to know where to procure a pure and genuine article, but also is equipped by training and education to know and advise prospective purchasers what products contain the vitamins they seek in the best combinations. The record shows that many vitamins lose their strength and vitality by exposure to light or adverse temperature. A pharmacist is equipped by training to know how best to preserve the beneficial qualities of these products. It is evident from the record that there is yet much to be learned about vitamins, particularly their mode of action. The legislature has already excepted many products from the operation of the pharmacy law. The time may come when medical research in this field will reach such a state of perfection that the legislature, in its discretion, may see fit likewise to except from the operation of the law preparations containing specified quantities of named vitamins that have been found to be harmless. For the time being, said the Supreme Court, we must be content to hold that pure and concentrated vitamins, natural or synthetic, prepared in the form of capsules, tablets, or liquids and carried either as a single vitamin or in combination with other vitamins in an excipient and so offered for sale to the public come within the definition of a drug in our pharmacy law and are not within any of the present exceptions thereto; as a consequence, they may not be sold or offered for sale in grocery stores. The pharmacy act, as applied to the facts now before us, is not so foreign to the protection of public health that it should be held to violate the constitutional provisions mentioned above.

Accordingly the declaratory judgment holding that vitamins may not be offered for sale in grocery stores was affirmed. *Culver et al. v. Nelson et al., 54 N.W. (2d) 7 (Minnesota 1952).*

BUSINESS PRACTICE

The following material is based on a public relations manual issued by the Public Relations Department of the American Medical Association.—ED.

OFFICE MANAGEMENT

There are two sides to the practice of medicine—the scientific side and the business side. Poor business practices often are at the bottom of patients' complaints about medical care and medical men. These might include: (1) poorly kept, inadequate records; (2) statements sent irregularly, sometimes incorrectly; (3) no follow-up on collections; (4) too much follow-up on collections; (5) unexplained charges; (6) use of unethical collection agencies; and (7) impersonal control of collection methods by untrained office personnel.

The physician who is systematic and business-like in the handling of office affairs of a nonmedical nature eliminates such public relations problems. Too often, business affairs are left to a secretary or are neglected. The physician who is indifferent to business matters soon finds that because he has kept inadequate records he not only is alienating patients but is in difficulty when tax collectors come around.

Medicine must never become a business, but there is a business side to medicine. Efficiency is nothing more than the operation of an office with a minimum of waste effort. Efficiency is good management—and good management is good public relations. To conduct a practice efficiently one must: 1. Have adequate space and facilities to treat all patients. 2. Employ adequate, qualified personnel. 3. Give careful attention to the business operation of the office. It is impossible to give patients satisfactory care unless there is sufficient office space and equipment. Some physicians set their sights too low when entering practice, taking the cheapest office location and trying to manage in cramped quarters with insufficient facilities. This is unwise. Some physicians wear themselves out by working in poorly arranged offices which could be easily redesigned for efficiency. Suggestions of sources of information on office lay-out and design can be secured from the state chapter of the American Institute of Architects.

A busy doctor should not try to do everything for himself. When he is busy, the first thing he neglects is his bookkeeping—a day-to-day task which should not be neglected. A doctor's records are the key to efficient management of his business. Carefully selected, well-trained (and adequately paid) personnel are public relations assets in the doctor's office.

Efficiency in the business operation of the office means that good records are kept, billing done systematically and regularly, and collections followed through. It means that letters are answered promptly, that insurance claims are filled out on receipt, that office bills are paid when due, that tax reports are filed promptly, and that attention is paid to all business details.

Assistance with the business side of medical practice can be obtained from professional management agencies throughout the country who specialize in helping physicians conduct their practices with efficiency, but it is not necessary to sign up for professional management services to adopt a few sound business practices.

Corticotropin in Active Rheumatic Carditis.—Wilson and associates present the results of the administration of corticotropin for 4 to 12 days to 28 patients in whom 32 attacks of active carditis occurred during the years 1949 to 1952. Seven patients who did not receive corticotropin served as controls. Antibiotic therapy was given to control intercurrent infections during the study period. The diet was salt-poor; fluids were limited to from 900 to 1,500 cc. Ascorbic acid was administered in doses of 150 mg. daily. Corticotropin was administered intramuscularly every six hours for an average period of seven days. The daily dosage varied from 1 to 5 mg. per kilogram of body weight. The following diagnostic criteria served to determine the presence of progressive symptoms and signs of active carditis: (*a*) the development of new systolic or diastolic murmurs, friction rub, or gallop rhythm; (*b*) progressive enlargement of cardiac chambers on fluoroscopic examination in the posteroanterior and oblique views at standard degrees of rotation; (*c*) diminishing cardiac reserve, i. e., dyspnea, decreased vital capacity, and enlarged or tender liver; and (*d*) electrocardiographic evidence of myocardial disturbance, i. e., prolongation of P-R interval, A-V dissociation, and T and ST changes. Active carditis was considered terminated when (*a*) there was fluoroscopic evidence of reversal of chamber enlargement and (*b*) new murmurs and friction rub disappeared and there was reestablishment of a normal cardiac reserve and return of the electrocardiogram to normal. Active carditis was considered to have recurred when any of the manifestations mentioned above were again observed. In all patients with active carditis of short duration, the progressive symptoms and signs were arrested during the first few days of corticotropin therapy, regardless of whether the corticotropin dosage was adequate or not. There was a recurrence of active carditis in the majority of patients who received inadequate therapy. Examination of 24 patients with active carditis who received adequate therapy revealed no overt clinical evidence of increased cardiac damage. There was reversal of chamber enlargement in 22 patients. Two patients with carditis of more than 10 days' duration, who did not exhibit progressive cardiac enlargement during the control period, showed no reversal of chamber enlargement. All patients were ambulatory within one to three weeks after therapy was discontinued. The cardiac status was maintained for 3 to 26 months, in the majority for more than 6 months. Of the eight patients who had inadequate therapy, five had a recurrence of active carditis. Three of the latter received a second course of corticotropin in adequate dosage, and, in two, carditis regressed spontaneously. The importance of early treatment is indicated by the failure to obtain reversal of cardiac enlargement in three patients with carditis of longer duration. Administration of corticotropin is followed by arrest and termination of active carditis without overt clinical evidence of residual cardiac damage, provided it is used before irreversible damage is sustained. The natural course of active carditis was favorably altered by decreasing both the severity and the duration of the attack.

Congenital Myasthenia Gravis.—According to Walker myasthenia gravis reaches its peak incidence in the third and fourth decades and is rare in the newborn. A survey of the literature revealed 17 cases of congenital myasthenia gravis. In 13 of these infants, the mother had myasthenia gravis and the infant had the typical picture. If these infants survive the neonatal period the disease disappears spontanously in a few days or weeks. It is possible that the mother's blood contains some substance that inhibits the formation of acetylcholine or accelerates its destruction. This substance is presumably destroyed or excreted by the infant during the neonatal period. Four reported cases of congenital myasthenia gravis were in children of nonmyasthenic mothers. The patient reported here belongs to this group. In such patients, the disease tends to be permanent. The patient whose case is reported was a 2-month-old girl who was hospitalized for the study of respiratory difficulty and inability to nurse. She was having considerable respiratory difficulty. The eyelids were slightly ptotic. There was a thin watery nasal discharge. The lips had a slight bluish tinge. The pharynx contained a large amount of watery secretions. The cry was feeble. Rhonchi were heard throughout the lung fields. Neurological examination showed hypoactive deep reflexes. Poliomyelitis, nuclear aplasia, amyotonia congenita, birth injury to the brain stem, and myasthenia gravis were considered. A therapeutic trial with neostigmine (Prostigmin) was begun. Within an hour respiration and expulsion of the secretions had improved considerably. She became more alert and active, and her partial ptosis disappeared. After much adjustment of the dosage schedule, the child was discharged four weeks after admission fairly well regulated on a regimen of 7.5 mg. of neostigmine bromide every eight hours, administered orally. Four days later she was readmitted; the dosage was modified to 5 mg. every four hours. At 8 months of age, she was still taking neostigmine and getting along fairly well.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Congenital Pulmonary Arteriovenous Aneurysm.—A review of the literature revealed 85 cases of congenital arteriovenous aneurysm of the lung. Anatomically, pulmonary arteriovenous aneurysms were observed in any of the lobes of the right and left lung; 27 of the 85 patients had multiple lesions with involvement of two and more lobes, and 21 had lesions in both lungs. These lesions were hemangiomatous in nature; the majority were hemangiomas of cavernous type with large vascular channels permitting varying degrees of arteriovenous shunt. Physiological disturbances, when present, were secondary to the shunting of unoxygenated blood back into the left side of the heart with resultant anoxemia and a polycythemic response of varying intensity. Symptoms, when present, were usually due to the anoxemia and polycythemia and less commonly to the aneurysm itself. Many of the abnormal physical and laboratory findings were also secondary to the anoxemia; the only positive physical finding in connection with the aneurysm itself was the presence of a vascular murmur heard through the overlying lung and chest wall in 52 of the 85 patients. Roentgenologic findings revealed that large lesions are easily demonstrable on routine roentgenography, but small aneurysms and telangiectases can probably not be demonstrated by roentgenologic means. Laminagraphy and angiocardiography are the most definite roentgenologic methods available for accurate identification of pulmonary arteriovenous aneurysms. Surgical removal of an aneurysm appeared to offer the only logical method of definite therapy, and this was employed in 44 of the 85 cases reviewed. Between 1940 and 1952, 10 patients with clinically evident pulmonary arteriovenous aneurysm were observed at the Johns Hopkins Hospital. In one patient the diagnosis was established by necropsy and in six by surgical intervention. In the remaining two patients the diagnosis seems reasonably certain. Two patients were members of the same family.

Roentgen Localization of Bronchopulmonary Segments.—Many inflammatory changes in the lungs, and quite often localized pulmonary tuberculosis, are limited to the anatomic and functional unity of the bronchopulmonary segments. In most cases one is able to localize the pathological process by this simple and safe method. Ten bronchopulmonary segments are the apical segment, the posterior segment, the anterior segment, the middle lobe lateral segment, the middle lobe medial segment, the apical lower lobe segment, the medial basal (cardiac) segment, and the anterior, lateral, and posterior basal segments. A scheme is established to determine by laminagraphy to which of these segments a pathological process belongs. Judgment must be carefully made in processes located on the border of two segments and in cases of dislocation following shrinking. It is often possible to present laminagraphically the segmental bronchi in their longitudinal axis by adding a suitable oblique position. The pulmonary focus appears then in its characteristic shape; the cavities are usually oval in shape because of the traction carried out by the bronchovascular bundle. The laminagraphic appearance of pathological changes of the smaller bronchi is discussed. Aeration of the lumen and thickening and distention of the bronchial wall are the most remarkable signs thus obtained.

Roentgen Therapy of Malignant Lymphoma.—From 1935 to 1945, 52 consecutive patients with histopathologically proved malignant lymphoma were admitted to the Carpenter Memorial Clinic in Wilmington, Del. Of the 52 patients 4 had follicular lymphoblastoma, and 3 of these survived for from 6 to 13 years. Nineteen patients had lymphosarcoma with seven five year survivals. Nineteen had Hodgkin's disease with nine five year survivals. Five had reticulum cell sarcoma, of whom one survived for 10 years. The remaining five patients could not be classified, but their clinical course was that of malignant lymphoma, and none survived. Nineteen of the 52 patients survived more than five years after admission, an absolute five year survival rate of 36.5%. Six of 25 patients treated from 1935 to 1940 were alive and without recurrence at the end of 1950, a 10 year absolute survival rate of 24%. The consideration of several variants of malignant lymphoma together is justified by their similar clinical course and the identical therapy required. Roentgen rays, generated at 200 kv. (peak) with 0.5 mm. copper filtration, were used at 50 cm. target-skin distance for superficial lymph nodes and at 70 cm. for deep lymph nodes. The fields treated varied somewhat in size but averaged about 200 square centimeters each. Patients were treated five or six days weekly, at the rate of 100 to

200 roentgens through each of two such fields. Of the four techniques employed, namely segmental therapy (irradiation of all the major lymph node areas), partial segmental therapy (treatment to the lymph nodes of half the body, above or below the diaphragm), symptomatic therapy (treatment to the lymph nodes producing the most distressing symptoms), and local treatment to a single group of grossly diseased lymph nodes, the first one was used whenever possible and was applied to 23 patients. Originally only low doses were given, but the authors now believe that 1,000 to 1,200 r should be given to all fields and from 1,200 to 1,800 r to the grossly diseased lymph nodes. The plan of treatment provides for two opposing fields over the deep lymph nodes, while superficial lymph nodes are treated through one field only. Sufficient unirradiated bone marrow is present to prevent agranulocytosis if only half of the body is treated in one series, and after an interval of one to three months the other half of the body may safely be treated to complete segmental radiation therapy. Treatment to grossly uninvolved lymph nodes is necessary if long-term palliation or cure is to be obtained. Eight patients in good general condition, with apparently limited lymph node involvement, were not given adequate segmental irradiation, and subsequently had recurrence in untreated or lightly treated lymph nodes. Three of these are now well after further therapy, one is under treatment for recurrence, and four have died. These eight cases are described in detail. More aggressive treatment is recommended, and a tabulation of all 52 cases is included.

Heparin in Venous Thrombosis.—Although it may be difficult to make a positive diagnosis of venous thrombosis in the early stage of the disease, treatment, in order to be successful, must be started at the first appearance of signs and symptoms. To delay it, in an attempt to make a more positive diagnosis, is to increase the morbidity and mortality rates. Since clinical experience with anticoagulant therapy has proved satisfactory, ligation of the inferior vena cava should be reserved for patients with septic thrombophlebitis, repeated pulmonary emboli, and pulmonary emboli occurring during anticoagulant therapy. In all other forms of deep venous thrombosis, anticoagulant therapy is recommended. Heparin is considered superior to bishydroxycoumarin (Dicumarol). The preferred method of administration of heparin (10 mg. per cubic centimeter) is by the intermittent intravenous technique (50 mg. of heparin every four hours). Concentrated heparin (200 mg. per cubic centimeter) is affective when given subcutaneously or intramuscularly, but subcutaneous injection is the preferred route of administration; this technique can be easily applied by nurses and does not cause discomfort to the patient. The preferred method of administration of heparin in gelatin (repository heparin) is 300 mg. given initially and 200 mg. given daily thereafter in the deep subcutaneous tissue on top of the deep muscle fascia. When it is necessary to terminate the anticoagulant effect of heparin after the administration of the drug in gelatin, an ice bag, fixed firmly with an elastic bandage over the site of the injection, will solidify the subcutaneous deposit of heparin in gelatin and arrest its absorption. Heparin therapy should be continued for several days after the patient is out of bed. It is believed that an increase in the coagulability of the blood occurs for one or two days after the termination of the heparin therapy. Unless heparin is continued until the patient is completely ambulatory, the formation of a new thrombus may occur after the cessation of the treatment.

Effects of Ligation of Major Veins.—Ligations of major veins were performed on 21 men between the ages of 26 and 72 years, most of them between the ages of 50 and 59, with a postphlebitic syndrome or an acute phlebitic process, with or without pulmonary infarctions. In 10 of the patients the inferior vena cava was ligated for control of repeated episodes of pulmonary infarction in 9 and for treatment of a postphlebitic syndrome in one. Of five patients in whom the common iliac vein was ligated, it was done for the treatment of a postphlebitic syndrome in four and for an acute phlebitic process in one. Of the remaining six patients, in five the superficial femoral vein was ligated bilaterally for control of repeated episodes of pulmonary infarction, and in the sixth it was done for control of an acute bilateral progressing phlebitis. The average follow-up for these patients was 462 days. Of the 21 patients 16 had had pulmonary infarctions that were clinically proven by roentgenograms; 12 of the 16 patients had had repeated episodes of infarction, and 4 had had only one such episode. Of the seven patients who had had pulmonary infarction during acute thrombophlebitis, it occurred during the first 10 days in four and after the 15th day in three. Recurrent infarction occurred in two patients after a major vein ligation. Of those two, one had a bilateral superficial femoral vein ligation on the seventh day after a transurethral resection of the prostate, and an inferior vena cava ligation was done because of the recurrent infarction. The other patient had a ligation of the left common iliac vein for the treatment of a postphlebitic syndrome of the left lower extremity. Sixteen days after this procedure he had a pulmonary infarction and 12 days later another infarction. This was followed by ligation of the inferior vena cava. There were no operative or postoperative deaths as a result of infarction or as a result of surgery. Hemorrhage was the chief operative and postoperative complication. Follow-up revealed slight restriction of activity in 9 of the 10 patients with ligation of the inferior vena cava, in 3 of the 5 with ligation of the common iliac artery, and in 1 of the 6 patients who had superficial femoral vein ligation. The patients who had a major vein ligation to prevent recurrent episodes of pulmonary infarction secondary to an acute thomboembolic process had less disablement and complaints than the group of patients who had a major vein ligation for a postphlebitic syndrome. Ligation of major veins to prevent recurrent episodes of pulmonary infarction is a lifesaving procedure and is usually not followed by enough disablement or impairment of function of the extremities to prevent the patients from returning to their previous occupations or adequate means of livelihood.

Liver Nodules Encountered at Laparotomy.—The Mixters stress that palpation in the liver for nodules or masses is an important part of the exploration of the abdomen prior to surgical treatment of the disease for which the laparotomy is performed. The size, shape, location, and consistency of such lesions will often give a clue to their true nature, yet these factors may also be misleading. Whereas the surgeon is very apt to submit for frozen section suspected metastases occurring elsewhere within the abdominal cavity, he is often prone to rely on his clinical impression where hepatic masses are concerned. To illustrate the importance and the difficulties of establishing an accurate diagnosis of liver masses discovered at laparotomy, the authors cite a number of cases seen by themselves or reported in the literature. Since clinical judgment as to the nature of hepatic nodules discovered at laparotomy is frequently in error, biopsy is indicated. The selection of the operative procedure and the prognosis must be based on the entire pathological picture, including the histological nature of the liver growth. Curative, rather than palliative, procedures should be carried out when biopsy or excision of nodules in the liver cannot be accomplished in otherwise operable extrahepatic malignant lesions. Isolated blood-borne metastases have been successfully removed from the lung, brain, and skeletal system, and evidence exists that solitary metastases also occur in the liver and that their removal is indicated when the primary tumor is controllable and there is no evidence of incurable spread elsewhere. Radical operative procedures of this type can be undertaken with the expectation that a number of patients will receive better palliation and that some will be cured.

Bone Marrow Changes After Splenic Irradiation in Leukemia.—The work reported by Gunz was undertaken with the aim of determining what changes take place in the bone marrow of leukemic patients in response to local irradiation of the spleen with roentgen rays. Studies were made on 15 patients with chronic myeloid leukemia and on 4 patients with other diseases. The bone marrow was usually obtained by sternal puncture, except in one patient whose iliac crest was punctured, and was carried out before and 80 minutes after the first and 24 hours after the last treatment. Patients were initially either untreated or had had no therapy during recent months. The site of aspiration was protected from stray radiation by means of lead rubber. Radiation factors varied from case to case, but all treatments were made with x-rays in the voltage range of 200,000 to 230,000. The investigation revealed two points: (1) changes in the composition of the bone marrow follow local x-irradiation of the spleen in some patients with chronic myeloid leukemia; and (2) inhibition of mitosis among the myeloid cells of the bone marrow can follow local irradiation of the spleen in these same patients although precautions have been taken to protect the marrow from direct irradiation. Of these two points the first is not unexpected considering the nature of the usual clinical response to splenic irradiation in patients with chronic myeloid leukemia; this consists not only of an involution of the enlarged spleen but also of a reduction in the raised number of myeloid cells in the peripheral blood and generally an increase in the red blood cell count. Mitotic inhibition in the marrow 80 minutes after irradiation of the spleen has not hitherto been described and if confirmed would constitute evidence in favor of that "indirect" action of x-rays in leukemia that has so frequently been suggested but not as yet satisfactorily demonstrated. Doses of direct (stray) irradiation received over the site of marrow aspiration were measured and found to vary between 1 and 3 r. Doses of this magnitude are not sufficiently high to produce mitotic inhibition in leukemic leukocytes. Moreover, no inhibition was noted among the erythroid cells. It appears unlikely, therefore, that the effect was caused by direct irradiation of the bone marrow. It is more probable that the action of the x-rays on the spleen was indirectly responsible. The mitotic inhibition was temporary. It could not be shown 24 hours after the last treatment in any of the cases investigated. The percentage of mitoses in leukemic marrow does not usually exceed that in normal marrow so that a permanent depression of the number of mitoses as a result of x-ray treatment is not likely.

Large Doses of Vitamin B_{12} in Discoid Lupus Erythematosus.—Seventeen cases of chronic discoid lupus erythematosus were treated with vitamin B_{12} in doses of 1,000 mcg. three times weekly. The treatment was painless and without side reactions, but most patients showed no change. Three showed very favorable response and some showed slight improvement. The results were inferior to those obtained with gold and bismuth salts. Vitamin B_{12} therapy has been discontinued for routine use.

Clinical Study of Neuroblastoma.—Oberkircher and associates have observed an unusual case of neuroblastoma since 1936. When the infant was 10 months old, the mother discovered a mass in the left upper abdomen that rapidly increased in size. One month later, hematuria and abdominal pain developed. Retrograde pyelography revealed a large mass in the region of the left kidney. A transperitoneal exploratory operation revealed a nonremovable tumor of the left kidney. Biopsy material was interpreted as Wilms' tumor. A series of roentgen ray treatments was given, and several months later a second attempt to remove the tumor failed. In succeeding years several additional series of roentgen treatments were given. At the age of 12 when the girl began to menstruate she still had a hard, fixed nodular tumor in the abdomen. The pathological material removed by biopsy in 1936 and then interpreted as Wilms' tumor of the kidney has recently been reexamined. The present diagnosis is neuroblastoma. The patient is now 17 years old, and her general condition is excellent. This case stimulated the authors to analyze the other cases of neuroblastoma at the Roswell Park Memorial Institute and the Buffalo Children's Hospital. On reviewing the 20 additional cases they were deeply impressed by the lack of response to treatment and the early fatal outcome in most of the cases. Neuroblastoma is one of the most frequent retroperitoneal malignant tumors in infants and children. In this series of 21 cases the primary tumor occurred in several areas of the sympathetic nervous system. Ten tumors were primary in the right adrenal. There were six involving the left adrenal. The remaining source of primary tumors were the thoracic sympathetic chain, 2; right kidney, 1; dorsal sympathetic chain, 1; and unknown, 1. The sex incidence is almost equal. Beside the patient who is now 17 years old and apparently well, another patient has survived five years and five months and at present is alive and well without evidence of disease. A third patient has lived one year and eight months since the diagnosis was established. This 19-year-old girl is alive and well at present. Apparently there is no adequate therapy for the neuroblastoma composed of immature cells. These malignant cells spread widely and rapidly, and the metastases make the outlook hopeless. Early surgery and irradiation are helpful in neuroblastomas composed of more mature cells. These tumors are more encapsulated and tend to remain localized. Bone marrow aspiration is of definite value both for diagnosis and prognosis. Nitrogen mustard offers very little in the therapy of this disease. When anemia, fever, loss of weight, and a palpable abdominal mass are present in an infant, one must be suspicious of neuroblastoma. This lesion is the commonest retroperitoneal malignant tumor in infants and young children.

Surgical Treatment of Adrenal Gland for Cushing's Syndrome.—It is now generally believed that all patients with Cushing's syndrome have hyperadrenocorticism with excess production of 11-oxysteroids. Of 19 female and 9 male patients between the ages of 18 months and 58 years with Cushing's syndrome admitted to the Cleveland Clinic since 1933, 2 had a malignant adrenal cortical tumor, 4 had a solitary adenoma of the adrenal gland, 2 had small adenomas occurring in otherwise hyperplastic adrenal glands, and the remaining 20 patients had normal or enlarged adrenal glands. The range in weight of adrenal tissue removed from these 20 patients varied from 2.5 to 27 gm. per gland, while the average weight of the adrenal gland from a normal person is considered to be between 2.5 and 7 gm. In three out of four cases Cushing's syndrome was due to adrenal hyperfunction with or without hyperplasia of the gland; the remaining patients had either a benign or malignant cortical tumor. Rarely, the initiating cause of the syndrome is a basophilic pituitary tumor. Most of the features of Cushing's syndrome can be produced by the prolonged administration of adrenocorticotropic hormone (ACTH), which stimulates the adrenal gland, or large doses of cortisone or hydrocortisone (Compound F). The diagnosis of Cushing's syndrome depends on clinical observations supported by laboratory evidence. Roentgenographic studies are helpful in locating a sizeable adrenal tumor but not a small one. Consequently, simultaneous bilateral adrenal exploration should be performed. Treatment consists of excision of a tumor if present or subtotal adrenalectomy. The operation can be done on both adrenals simultaneously without undue risk. All patients should be given a protective dose of cortisone, 100 mg. intramuscularly about 12 hours before surgical intervention, and this should be repeated a few hours before the operation. Doses of about 50 mg. of cortisone should be given every 6, 8, or 12 hours after the operation depending on necessity. There is usually sufficient desoxycorticosterone-like action in cortisone to supply the daily need of this hormone in most patients; it may be necessary to give desoxycorticosterone in doses of 1 to 3 mg. daily to patients who have low serum sodium values not sustained by added salt in doses of 4 to 6 gm. daily as enteric coated salt tablets. At present it is not considered necessary to perform bilateral total adrenalectomy unless the disease is progressive after subtotal adrenalectomy (with about 90% of adrenal tissue removed) and a threat to life. With adequate resection of adrenal tissue the skin of the patient becomes normal in color and texture, hirsutism disappears, muscles strengthen, obesity vanishes, menstruation returns in women, glucose tolerance tests return to normal, and patients with diabetes show improvement. Osteoporosis does not show the same rate or degree of improvement, and hypertension does not always improve after subtotal adrenalectomy. Results were encouraging in eight patients with Cushing's syndrome owing to adrenal cortical hyperplasia treated in the last year and a half since cortisone came in use. One required secondary total adrenalectomy for control of the disease, and one patient was improved but died nine months after operation because of shock from an uncontrolled duodenal ulcer hemorrhage. The remaining patients are all improved or have too short a follow-up to be of value.

Retroperitoneal Tumor as Cause of Low Back and Leg Pain.—Anderson and Alpers report on four patients to define the neurological features by which tumors in the retroperitoneal space may be recognized. The first patient experienced a sharp pain in the low back on attempting to lift a heavy log. The original sharp pain was replaced by a constant dull ache, aggravated by standing and radiating into both groins and into the right leg. The right kidney was enlarged, and intravenous urography revealed upward displacement of the right kidney. Necropsy established a retroperitoneal lymphosarcoma. The second patient had a history of back pain radiating into the right groin and testicle and accompanied by an aching in the anterior and lateral aspects of the right thigh. In spite of the lateral deviation of the upper portion of the right ureter and upward displacement of the right kidney, the diagnosis was not made at the time of his first examination. Because of the persistence and progression of his complaints, the urograms were repeated and revealed more lateral and upward displacement of the right ureter and kidney and, in addition, a definite bulging of the right border of the psoas muscle. Operation revealed a retroperitoneal fibrosarcoma. The third patient had right back and leg pain. She was suspected of having involvement of the roots of the right sciatic nerve by an intervertebral disk, but myelography was normal. After further progression of symptoms, roentgenographic evidence of a calcifying, eroding tumor was found in the right sacrum. In the fourth patient, the diagnosis was made on the basis of clinical findings. Because of spread of pain beyond the limits of the sciatic distribution, the absence of the patellar reflex, and the evidence of testicular and scrotal swelling, further studies led to a diagnosis of retroperitoneal tumor involving the right psoas muscle and extending into the right lumbosacral plexus. Operation revealed epidermoid carcinoma obstructing the right ureter and involving the right psoas muscle. On the basis of over 500 cases of retroperitoneal tumors reported in the literature, the usual symptoms of such tumors consist of vague digestive disturbances, progressive weight loss, weakness, constipation, urinary frequency and urgency, and complaints of abdominal swelling. Less common are pain in the lower abdominal quadrants, edema of the lower limbs, weakness with muscular atrophy of the leg, difference in surface temperature of the extremities, and back and accompanying leg pain. Although diagnosis of retroperitoneal tumor is ordinarily made on other than neurological features, there are instances in which neurological symptoms predominate.

Heart in Myxedema.—Changes in the size and configuration of the shadow picture of the heart in 27 patients with heart disease and variations in the electrocardiogram in 28 patients with intractable angina pectoris or congestive heart failure were studied before and for 2 to 53 months after the occurrence of myxedema that was induced in each patient by one or more doses of radioactive iodine (I^{131}). All patients were distinctly hypothyroid and were maintained at basal metabolic rates of -15 to -25% on 6 to 90 mg. of desiccated thyroid daily. Alterations in heart size and electrocardiographic pattern were correlated with the level of hypometabolism as determined by the clinical state, basal metabolic rate, serum cholesterol, thyroid uptake of tracer doses of I^{131}, and serum protein-bound iodine. Ten of 13 patients who experienced striking or significant relief of angina pectoris after induction of hypothyroidism showed no increase in cardiac size after 2 to 48 months of hypometabolism. Two others presented no enlargement of the heart in 26 and 38 months of hypometabolism during which a good or excellent therapeutic result was obtained; subsequently, cardiac enlargement was noted in these cases during an exacerbation of angina pectoris and congestive heart failure. Five of six patients with angina pectoris not benefited by I^{131} therapy showed a progressive increase in the size of the heart. Six patients with chronic congestive heart failure showed no cardiac enlargement during most of 19 to 53 months of hypometabolism. In two patients an increase in the size of the heart was observed only shortly before death after 22 and 31 months of hypothyroidism, during which definite therapeutic improvement was experienced. In two patients with both angina pectoris and congestive heart failure, radioactive iodine-induced myxedema was followed by striking therapeutic benefit despite the progressive cardiac enlargement. The development of myxedema was accompanied by a decrease in electrocardiographic voltage, flattening or inversion of T-waves, and a slight decrease in the QT interval. Changes in the electrocardiogram regressed after the administration of small doses of thyroid. Thereafter, despite the hypometabolism for months or years, no further progression in the electrocardiographic pattern occurred. The data indicate that the "myxedema heart," in the sense of a condition precipitating angina pectoris or congestive heart failure or accompanied by pronounced electrocardiographic and roentgenologic changes, does not occur in patients with prolonged, controlled radioactive iodine-induced hypothyroidism.

Treatment of Meningococcemia.—A classic case of acute meningococcemia with shock (Waterhouse-Friderichsen syndrome) is described in a 17-year-old boy. An intravenous infusion of arterenol (Nor-Epinephrine) in a concentration of 4 mg.

per liter of 5% dextrose solution was used successfully over 60 hours to combat peripheral vascular collapse. Physiological studies of adrenocortical function during the acute stage of the illness and after recovery indicated no failure of the adrenal cortex, even in the presence of shock, which responded to arterenol but not to parenteral adrenocortical replacement therapy with aqueous lipoadrenal extract. There was probably no serious impairment of the tested adrenocortical function during the acute phase of the illness of the author's patient. Thus the pathogenesis of the peripheral vascular collapse in the Waterhouse-Friderichsen syndrome remains an unsolved problem. The use of a continuous infusion of arterenol was probably a life-saving measure and prevented irreversible shock and serious renal damage from prolonged ischemia. It is suggested that the use of this vasopressor agent be considered in all cases of septicemia with peripheral vascular collapse, especially when adequate trial with blood transfusions, plasma, fluids, and adrenal substitution therapy has been unsuccessful in forestalling shock.

Experience with Carbomycin.—The greatest activity of carbomycin (Magnamycin), a new antibiotic produced by the Streptomyces halstedii, is against gram-positive bacteria. This activity is greater than that of oxytetracycline (Terramycin) but less than that of penicillin. Some strains of Staphylococcus aureus develop resistance to carbomycin readily, and there is a high degree of cross resistance with erythromycin. Studies were made on adults with normal heart, liver, and kidney functions to whom carbomycin was given. Oral doses smaller than 500 mg. did not produce any antibacterial activity in the serum. But detectable serum concentrations were found in two-thirds of the persons who received it orally in doses greater than 500 mg. and in almost all those who received it intravenously in doses of 400 mg. diluted in 20 cc. of isotonic sodium chloride solution. The drug was always recovered from the urine in total amounts equal to 0.5 to 2.5% of the dose administered. The authors used carbomycin to treat 57 patients with acute infections due to the pneumococcus and to alpha-hemolytic, beta-hemolytic, and nonhemolytic streptococci. A daily dose of 2 gm. was used except for a few more acutely ill patients who received 3 gm. daily for several days or 400 mg. intravenously every 6 to 8 hours for from 24 to 96 hours. Good results were obtained in 34 of these patients. They were good in those with acute bronchitis; the temperature returned to normal within 24 hours and the sputum improved more gradually. There was a good clinical response in patients with acute follicular tonsillitis. The effects were poor in patients with subacute bacterial endocarditis, and there was no definite symptomatic improvement in those with urinary tract infections due to the streptococci faecalis and pyogenes. The response in patients with staphylococcal sepsis was not striking, and it was poor in patients with pneumonia whose sputum revealed Hemophilus influenzae. The bacterial colonies were increased in five of the last-named patients during the therapy. Side-effects consisting of gastrointestinal disturbances and skin eruptions occurred in 15 patients, but they were never severe. There was no clinical evidence of central nervous system toxicity or changes in reflexes. At present the use of carbomycin should be limited to those patients who are hypersensitive to penicillin or the newer antibiotics and to those with infections that have proved, or are frequently, resistant to penicillin, chlortetracycline (aureomycin), and oxytetracycline. An initial dose of 500 mg. (the maximum tolerated dose) every six hours should be given at once and, when possible, it should be supplemented initially with parenteral administration of the drug.

Bichloride of Mercury Poisoning and BAL Therapy.—A 28-year-old woman with a history of normal heart and kidney functions was hospitalized in a state of mild shock 2½ hours after she had ingested four tablets (2 gm.) of bichloride of mercury. Severe gastrointestinal bleeding was present, and both the fecal material and the vomitus gave a positive test for blood. About 240 cc. of brown, guaiac-positive urine was removed. Oxygen and parenteral administration of fluid cleared the shock-like state. Dimercaprol (BAL) was given three hours after she had ingested the tablets. Progressive acidosis and uremia developed, and early signs of potassium intoxication appeared. The gastrointestinal bleeding became massive. Dimercaprol and fresh blood transfusions, chlortetracycline (aureomycin), vitamin K, corticotropin, pyribenzamine, rutin, ascorbic acid thrombin, and absorbable gelatin sponge (Gelfoam) had no obvious effect on the bleeding or on the results of hematological studies. A forced dilution therapy was initiated, and the patient was given excessive quantities of fluids. The blood urea nitrogen level was lowered and the hemorrhage was brought under control. During the fluid therapy, the urine volume increased and 84 gm. of total nitrogen were excreted in 72 hours. There was a dramatic clinical improvement. The patient was discharged 56 days after admission. Follow-up examinations during three months revealed no significant gastrointestinal abnormalities other than a low specific gravity of the urine. The exact cause of bleeding in uremic gastroenteritis is still unknown. The excretion of urea into the gastrointestinal tract, the action of the intestinal bacteria, and the generalized bleeding tendency associated with the uremic syndrome are important factors. According to some authors, the bleeding is caused by the excretion of urea into the gastrointestinal tract. Here it is hydrolyzed by the intestinal bacteria into ammonia and carbonic acid, and it is the resulting ammonium carbonate that directly damages the mucosa. Dimercaprol should be given as early as possible to patients with bichloride of mercury poisoning. An initial intramuscular injection of 300 mg. followed by two or three 150 mg. injections during the first 12 hours and one or two such injections in the next 12 hours is the best plan of therapy. Then 150 to 300 mg. may be administered for one or two more days depending on the patient's condition. Whether therapy with dimercaprol should be continued after oliguria develops remains to be established. The authors discontinue it if the patient's condition permits. Otherwise they continue it with doses reduced to 75 to 100 mg. daily in two or three divided doses. Administration of the drug is then immediately discontinued if any toxic reaction appears. Forced fluid therapy is indicated in the presence of severe hemorrhage and impaired renal function in order to rapidly lower the blood urea nitrogen. Adequate amounts of dimercaprol given as soon as possible and combined administration of large quantities of fluid should reduce to a minimum the occurrence of renal failure.

Perforated Gastric Ulcer During Cortisone Therapy.—Kerdasha reports the case of a man, aged 63, in whom perforation of a gastric ulcer occurred while he was receiving cortisone therapy for rheumatoid arthritis. There was no proof that the ulcer did not exist prior to cortisone therapy. However, the initial appearance of an acute perforation 21 days after the start of cortisone administration in a patient who had no prior gastrointestinal symptoms suggests that the ulcer developed after therapy was begun. The most striking features were the patient's good general appearance, his feeling of well-being, and the moderately severe pain in the presence of a board-like abdomen due to peritoneal irritation of some 19 hours' duration. Operation disclosed a partially sealed perforation in the anterior antral portion of the stomach. The perforation was closed with interrupted atraumatic absorbable surgical sutures; a tag of omentum was tied over the repaired area. The peritoneal cavity was thoroughly aspirated. The incision was closed without drainage. The patient did well; he was given 500 cc. of blood after the operation and made an uneventful recovery. Penicillin and streptomycin were given in 300,000 units and 0.5 gm. doses twice a day for five days. Extreme caution is urged in the use of adrenocortical steroids in the treatment of disease, particularly if associated with peptic ulcer.

Multiple Curling's Ulcer.—Bothe and Magee report the case of a 68-year-old woman who had been scalded in a bath tub and who had sustained second and third degree burns of the buttocks, perineum, and posterior portions of both lower extremities, including the feet. The patient had lived in a nursing home for nine years because of flaccid paralysis of the left arm and leg, extensive hypertrophic arthritis, and generalized arteriosclerosis. She had no gastrointestinal symptoms prior to admission to the hospital. The shock was treated, and pressure dressings were applied to the burns to preserve tissue fluid, but after the fifth day the burns were treated by the open method. On the 33rd hospital day, the patient vomited 220 cc. of dark blood. Small amounts of hematemesis followed daily. This bleeding was attributed to a Curling's ulcer, and medical management was instituted. She failed to respond to treatment. Bronchopneumonia developed, and the woman died on the 44th hospital day. At autopsy, it was found that the esophagus was coated with blood. The mucosa at the junction of the esophagus and stomach was eroded over an area of approximately 1.5 cm. The lesser curvature of the stomach contained a 2.5 cm. ulcer. Numerous ulcerations were present over the lateral walls and lesser curvature of the stomach from cardia to antrum. A single ulcer approximately 1 cm. in diameter lay astride the pylorus. Distal to this the gastrointestinal tract was normal. A diagnosis of multiple Curling's ulcer was made. This case is noteworthy not only because of the presence of multiple ulcers but because this extensive ulceration did not make itself known until the 33rd day after the burn, which is much later than Curling's ulcer usually appears. The occurrence of this type of ulceration in a person with long-standing hemoconcentration, in whom death was finally attributable to pulmonary emboli, suggests that embolic phenomena may be responsible for Curling's ulcerations.

Safety of Serum Globulin with Respect to Hepatitis.—Immune serum globulin is prepared commercially by two processes: (*a*) salting-out, e. g., by means of ammonium sulfate, and (*b*) by the cold-ethanol process or a variation thereof. Blood obtained either by venipuncture or by extraction from placentas is used as the source material. The requirements of the National Institutes of Health for immune serum globulin stipulated that pools consist of at least 500 individual contributions. In view of the fact that approximately one person out of 300 receiving blood transfusion may develop hepatitis, it might be expected that many of the pools of plasma used in the manufacture of immune serum globulin would be infected with the agent, or agents, of homologous serum hepatitis. Although experience indicates that the incidence of homologous serum hepatitis following administration of immune serum globulin must be low, it was deemed advisable to determine the infectivity of immune serum globulin with reference to homologous serum hepatitis by inoculation studies in human volunteers. Material from a pool of infected plasma, approximately 130 liters, was used in the studies on the safety of plasma and its derivatives. Approximately 16 liters of this plasma were fractionated by the cold-ethanol process. The immune serum globulin so prepared was subjected to the required tests for sterility, safety, and pyrogenicity. This material was then inoculated subcutaneously into 10 volunteer subjects, each of whom received 2 ml. Simultaneously five volunteers in a control group each received 1 ml. of the original plasma from which the globulin had been produced. None of the subjects who received globulin developed hepatitis, with or without jaundice, while one of the five in the control group developed hepatitis with jaundice, and a second person in this control group developed positive hepatic tests suggestive of hepatitis without jaundice. Hepatitis with jaundice also developed in two of five subjects who were inoculated with 1 ml. amounts of a 1/1,000 N saline dilution of plasma from the same vial as that administered to the aforementioned control group. Thus it was demonstrated that immune serum globulin produced by the cold-ethanol method from proved infectious plasma failed to produce hepatitis in 10 volunteer subjects.

Quinacrine (Atabrine) in Discoid Lupus Erythematosus.—Miller says that the spectacular success obtained with quinacrine (Atabrine) by Page in 1951, reported in *The Lancet* (2:755 [Oct. 27] 1951); abstracted in The Journal ([Feb. 2] 1952, p. 409) met with some skepticism, owing to the fact that several new agents have been tried in recent years in the treatment of lupus erythematosus but none has seemed to stand the test of time. A pharmacist, who had had chronic discoid lupus erythematosus with extensive involvement of the skin for three years first learned of this report in February, 1952. This man had received much therapy including gold and cortisone, but there had been little amelioration of symptoms or of skin eruption. Self-medication with quinacrine was begun, and after only a few weeks the patient became enthusiastic about his improvement. By May, 1952, there was a definite and marked objective improvement. Treatment with quinacrine in 9 of 10 patients, whose histories are presented here, showed great improvement; only one patient failed to improve. In three patients the lesions cleared completely, and in the others there was a gradual but steady involution of plaques. The sedimentation rate, however, has not been favorably influenced although patients appear to be greatly improved subjectively. In an addendum, the author states that since the submission of this report an additional 18 patients with lupus erythematosus have been treated with quinacrine. Results in the treatment of discoid lupus erythematosus have continued to be excellent, although only 4 of the 28 patients treated with quinacrine have been able to discontinue use of the drug. A number of patients have now taken quinacrine for more than 10 or 12 months. Although the effects of quinacrine are far from ideal, it seems to be superior to other treatments.

Amebic Granuloma of Rectum Simulating Carcinoma.—Infection of the intestinal tract by Endamoeba histolytica may result in the development of a chronic hyperplastic process, with or without abscess formation, that is known as amebic granuloma or ameboma. These lesions may cause intestinal obstruction and may be confused with carcinoma. The author cites the history of a man, aged 30, who was admitted to Letterman Army Hospital on July 1 with abdominal pain as his chief complaint. Abdominal pain and distention had been present since the middle of May. The patient was admitted to another hospital on June 21, and a diagnosis of tumor of the rectum was made there. A Frei test was negative. A stool examination for parasites and ova was ordered, but apparently was not done. On transfer to Letterman Army Hospital he had lost 42 pounds and had vague abdominal tenderness, but no mass was palpable through the abdominal wall. Rectal examination disclosed a firm mass posteriorly, on the right side, about the size of a lemon. It seemed to involve the wall of the rectum. His temperature varied up to a maximum of 100 F; his leukocyte count ranged up to 20,900, with 83% neutrophils; and his hemoglobin level dropped to 7 gm. after the onset of an intestinal hemorrhage that characterized the terminal stages of his illness. A barium enema revealed a constant filling defect encircling the upper half of the rectum. During proctoscopy an obstruction that could be bypassed on the left side was encountered 5 cm. above the anal orifice and a mass about 6 cm. in diameter, which was apparently in the rectal wall. On July 23 an exploratory laporatomy was performed. The organs in the pelvis were an adherent mass. This mass extended from the posterior surface of the urinary bladder to the sacral promontory, and the lower sigmoid went directly into it. A sigmoid colostomy was performed and division of the colostomy loop was completed on Aug. 4. The patient died one month later. At autopsy, scrapings from the margin of an ulcer in the rectosigmoidal mucosa revealed trophozoites of E. histolytica, and microscopic examination of the bowel showed colonization by the same organisms. In retrospect, the elevated leukocyte count, with a high per cent of neutrophils, and the febrile reaction perhaps should have suggested an inflammatory process. It is possible that the ulcer of the rectum noted at autopsy was present at the time of proctoscopy, but that it was not seen because of its location above and behind the elevated and indurated mass infringing on the lumen of the bowel. Amebic granuloma should be considered in the differential diagnosis of obstructive or deforming lesions of the large bowel.

Treatment of Arachnidism with Cortisone. C. E. Watson and J. E. Stone.—p. 258.

Hypotensive Anesthesia.—Brunschwig and Boyan attempted to reduce blood loss in radical excisional procedures by controlling hypotension. They induced hypotension during general anesthesia in a series of 68 cases by intravenous injection of hexamethonium bromide. The operations performed included radical hysterectomy and pelvic lymph node excision, total or partial pelvic exenteration, abdominoperineal resection of colon and hysterectomy, pancreatoduodenectomy, partial hepatectomy, total vulvectomy and radical inguinal node excision, thoracoabdominal gastroesophagectomy, bilateral adrenalectomy, excision of various types of pelvic and abdominal tumors, exploratory laparotomy, and radical mastectomy and neck dissection. The results were excellent in 36 cases and good in 17. The effect was undetermined in 5 cases, and in the remaining 10 there was either no apparent hemostatic effect or hypotension failed to develop. It seemed that younger persons do not respond as well as middle-aged persons. Hypotensive anesthesia does not seem necessary in routine procedures, and should be reserved for ultraradical surgery in which extensive dissections and large raw surfaces occur. Patients subjected to hypotensive anesthesia are in a very susceptible status in so far as the circulatory system is concerned, and therefore this type of anesthesia must be conducted by a physician specialist in anesthesiology.

Chronic Barbiturate Intoxication.—Eleven patients who could be called true barbiturate addicts were observed during 1951 at the Medical Center with which Milburn is connected. Six were addicted to barbiturates only and five were addicted to both barbiturates and alcohol, the barbiturate component predominating. The period of habitual use of the drug ranged from 3½ to about 17 years. The amount ingested per 24 hour period ranged from 4.5 to 17.5 grains (0.3 to 0.5 gm.). In only two cases was there an accurate history of therapeutic administration previous to addiction. Constitutional psychopathic inferiority or character disorders, such as anxiety, dependency, inadequacy, compulsive features, depressive tendencies, and character disorders with schizoid trends, were present in all. The clinical picture was that of moderately acute intoxication, that is, cortical depression and cerebellar dysfunction. Capacity for abstract thought and ability to think concretely were impaired. Defective judgment, somnolence, and confusion were present in all. There was neglect of the social amenities, and some patients were dirty and unkempt. Withdrawal of the barbiturate was attempted in all, but four left the hospital before emotional stability had been established. An abstinence syndrome always developed after sudden reduction or complete and abrupt withdrawal of the drugs. Petit mal or grand mal seizures occurred in some of the patients. One patient died after a succession of seizures. Six patients became acutely psychotic between the fourth and eighth day of abstinence. In many respects their symptoms resembled those of acute alcoholic hallucination. Treatment of barbiturate addiction should be carried out in a hospital where adequate control of the patient can be maintained. Withdrawal of the barbiturates is best effected by gradual reduction. If, during withdrawal, the patient becomes highly nervous, has tremors, anxiety, and severe insomnia, reduction of dosage should be stopped. If convulsions and hallucinations occur, the dosage should be raised and one or two doses administered intravenously. The hallucinations usually disappear by the fourth or fifth day following complete abstinence after gradual withdrawal. In the last phase of treatment, rehabilitative and psychotherapeutic measures should be instituted.

Morphology of Vaccinia and Myxoma Viruses.—According to Farrant and Fenner, there is general agreement among virologists that, from the viewpoint of taxonomy, morphology is the most important single property of the animal pathogenic viruses. Study of stained smears of the elementary bodies of the virus of infectious myxomatosis with the light microscope established that in appearance they resembled the elementary bodies of vaccinia. This similarity was confirmed by electron microscopic examination of these viruses, which revealed that the elementary bodies of both were almost identical in size and exhibited the brick-shaped appearance characteristic of the pox viruses. Despite this evidence, myxoma is not generally classified as a pox virus but has usually been grouped with Rous sarcoma and Shope papilloma viruses as a tumor-producing agent. Detailed studies, by one of the authors, of myxomatosis in European rabbits revealed that there was a closer similarity between the pathogenesis of myxomatosis and the pox diseases than had previously been recognized. A more detailed electron microscopic examination of myxoma virus revealed that the elementary bodies of myxoma and vaccinia viruses are identical. Both have the brick shape characteristic of the pox viruses. The dimensions of the osmium-fixed particles of the two viruses are given. Myxoma particles contain dense pepsin-resistant central bodies similar to those demonstrated in vaccinia and fowlpox viruses by other workers. These facts, together with the recent demonstration of a close similarity between the pathogenesis of myxomataosis and the pox diseases, indicate that myxoma belongs to the pox group.

Familial Incidence of Congenital Malformation of Heart.—The familial incidence of congenital heart disease was recorded for 425 families which contained 431 probands born to Birmingham mothers between 1940 and 1949. The diagnosis of congenital malformation of the heart was established in the proband by postmortem examination, at operation, or clinically by a consultant physician. There were six affected by congenital heart disease (18 per 1,000) among 342 siblings born after the proband. This is approximately six times the incidence (3.2 per 1,000) in the general population of births. The incidence of malformations other than congenital heart disease was not raised in siblings of probands. The nature of the cardiac defects was fairly reliably diagnosed in five families with two affected members; in three of the five families the lesions were identical in both persons affected. This evidence suggests that the risk of recurrence of the same cardiac malformation may be greater than the risk of a different one. Five confirmed and 13 unconfirmed cases of congenital malformation of the heart were identified among 4,143 first cousins of probands. Of 834 parents, 14 were said to have congenital heart lesions. Further clinical examination indicated that eight of them were normal, four had rheumatic heart disease, and only two had congenital heart lesions. There were two marriages of first cousins among 424 marriages of parents of probands; in both cases, the proband had dextrocardia and transposition of the viscera. There were seven patients with dextrocardia among the probands, and the high incidence of consanguinity of parents in these cases provides support for Cockayne's suggestion that this condition may be inherited as a recessive.

The Poliomyelitis Complement Fixation Test.—The studies described are preliminary to work with human serums. The author stresses that the technique of Fulton and Dumbell, in which drops of reagents on perspex sheets are used, was successfully applied to poliomyelitis antigen-antibody systems. The different ways of performing the test are described. The antigen was an aqueous suspension of the brains of very young mice infected with the "adapted" MEF_1 strain of type 2 poliomyelitis virus; unlike that of Casals and Olitsky, it was not acetone-ether extracted. In two-dimensional complement fixation tests, with varying concentrations of complement and serum, as in conventional one-dimensional tests with a single complement dose, specific fixation was obtained with the unextracted antigen and hyperimmune Lansing and MEF_1 (type 2) antiserums. No specific fixation was detected with hyperimmune monkey serums against type 1 and type 3 poliomyelitis viruses. A few human serums were examined. In general those from children and adults with no history of recent poliomyelitis showed no fixation with the unextracted poliomyelitis antigen although some Wassermann positive serums gave variable nonspecific reactions. Paired serums from patients showed mostly slight, but in some cases definite, fixation with the type 2 antigen in one or other specimen. Heating at 56 C for 30 minutes destroyed the infectiousness of the antigen for mice, as did ultraviolet irradiation for 5 minutes. Heating reduced the titer slightly, whereas this amount of irradiation did not.

Conservative Treatment of Hemangiomatous Nevi.—Wallace observed 300 patients with various forms of hemangiomas appearing soon after birth. In 95% of these, follow-up could be continued for an average of seven years. He excludes from observation arterial hemangiomas, diffuse hemangiomatosis, gigantism, and multiple familial telangiectasia. He classifies the lesions into two groups; flat and raised. The flat group includes the spider nevus (stellate hemangioma), which is rarely present at birth. It may appear for the first time in adult life and it may undergo spontaneous regression in childhood. This group also includes the salmon patch (erythema nuchae), which is pale pink, occurs especially on the nape of the neck and forehead, and fades in a few months, and the port-wine stain (naevus flammeus), which is of deeper color and consists of a thin layer of capillary tissue in the dermis. The port-wine stain is permanent. A rare variant of this is a thicker plum-colored nevus often associated with intracranial lesions, the Sturge-Weber syndrome. Application of thorium X is the only effective treatment in port-wine stains. In about two-thirds of the patients treated with thorium X the intensity of the staining was greatly reduced; in the remaining one-third improvement was minor. These results although unsatisfactory are superior to those obtainable with freezing, x-ray, or even plastic surgery. The latter treatment, however, is the only one that gives hope of improvement in the plum-colored lesions of the Sturge-Weber syndrome. Treatment is most controversial in the raised types of hemangioma. The author observed 208 patients with strawberry nevi, often multiple, and 98 patients with 121 cavernous nevi of which 78 had some superficial capillary element. In both types the nevus may appear at or a month or two after birth and may grow out of proportion to the child. After a few months, this disproportionate growth ceases and is followed by gradual involution over the next few years. Most of the involution occurs within the first two or three years of life but may continue up to the age of 7 years. In strawberry hemangioma, the appearance of grey flecks is the earliest sign of spontaneous involution. Ulceration occurred in a few patients but did not cause serious trouble and was not comparable to the ulceration following many forms of treatment. The danger of strawberry or cavernous hemangiomata enlarging to such a degree that they injure vital structures has been greatly exaggerated. There is seldom, if ever, any justification for the mutilating surgery that is occasionally performed. Most of the recorded reports of malignant change in these hemangiomas bear the imprint of panic combined with inadequate knowledge of their natural history. There is, however, a very rare type of strawberry hemangioma that does not alter in size out of proportion to the patient either during infancy or childhood but in which maliginant change has been recorded at or after puberty, but never before. The general impression of these lesions is that they are redder than the usual and at no time show any signs of involution. It is, therefore, fairly easy to recognize such very rare lesions by the age of 6 or 7 years, and excision seems to be indicated.

Tylosis.—According to Dencer, tylosis is a rare congenital hyperkeratosis affecting the hands and feet. The part most involved in the feet is the weight-bearing area. The thickening tends to spread up and to encase the heel. Cracks are generally present, and these often become infected. This condition may produce little or no disturbance, or the thickening of the skin of the hands may seriously interfere with finer movements of the fingers and reduce tactile sensibility. The soles tend to be more painful than the palms, and frequent attention may be necessary to enable the patient to remain ambulant. The disorder may spread to the dorsum of the fingers or toes, and frequently the nails are attacked. They become thick, opaque, raised up from the nail bed by a horny accumulation beneath them. In some cases the associated onychodystrophy gives rise to symptoms severer than the skin lesion. The condition should be distinguished from the acquired hyperkeratoses due to the excretion of arsenic, from Mal de Meleda seen on the Dalmatian coast, from hereditary disseminate keratoma, and from disseminate keratoderma of the palms and soles. Before presenting the histories of five patients with tylosis that he observed, the author cites other reports on this condition and gives particular attention to the possible role of vitamin A deficiency in the causation. The five cases presented occurred in two families in which the condition appeared in each of several generations. The treatment so far has been largely palliative. Local measures, such as rubbing with fine sandpaper or softening the skin with salicylic acid and other keratolytics, may keep the condition under control. Vitamin A therapy has been tried with doses of 100,000 units daily for long periods. Superficial x-ray therapy has been tried but is not a completely satisfactory measure and is not without risk. Temporary spontaneous cures have been known to occur, and temporary cure has also occasionally resulted from prolonged bed rest. The author presents the history of one woman in whom the condition was so severe that she was unable to bear any weight on her feet, and she had to do all her housework on her hands and knees. Complete excision and grafting was tried and proved very satisfactory.

1952 Epidemic of Poliomyelitis in Essen.—In 1952, 318 cases of poliomyelitis were observed in 255 children and in 63 adolescents and adults. The total mortality rate was 8.88%. In the different districts of the city, the mortality rate varied from none to 22.6%. Of the 318 patients, 8 were brothers and sisters ("fraternal cases") and 5 were children who had played together ("paired cases"). Close contact may play a part in the causation of the infection. Trauma in the widest sense of the word and overexertion are of definite importance during the incubation period, as was proved by the histories of 16 patients. Of 242 hospitalized children, 111 had a nonparalytic type of the disease. Of 126 paretic patients, 51 had an "ascending" type of paresis. Five children had primary polioencephalitis. The simultaneous presence of a high cell count and protein values in the cerebrospinal fluid suggests an unfavorable prognosis. In patients with these findings, a very rapid ascent of paresis was frequently observed. The bulbar types with much less pronounced findings in the cerebrospinal fluid have an unfavorable prognosis, if they are associated with vasomotor weakness. Physical and mental strain should be avoided during the critical stage of the disease. Two cases of late paralysis were apparently caused by actions contrary to this rule. In one of these patients the exacerbation resulted from too early physical strain. Of 16 patients placed in a mechanical respirator, 11 died and 5 improved. The mechanical respirator is particularly indicated in patients with spinal respiratory paralysis, but not in patients with bulbar respiratory paralysis. Children who could not count further than six in one breath and who had dyspnea when resting and pulmonary roentgenologic manifestations were placed in the mechanical respirator. Temporary application of a mechanical respirator is recommended for patients in deep coma with superficial breathing. The "electrolung" proved beneficial as a preparatory treatment before taking the patient out of the mechanical respirator. It was also useful in the after treatment of paresis of the diaphragm and abdominal muscles.

Hormone Therapy of Carcinoma of Prostate.—Observations on women with cancer given large doses of male sex hormone and animal experiments in which the Fallopian tubes or the spermatic ducts were severed with resulting hypofunction of the thyroid, suggested the use of desiccated thyroid or thyroxin in patients with carcinoma of the prostate in addition to female sex hormones or synthetic substitutes. This idea is based on the concept that the effect of the sex hormone on the tumor tissue may thus be increased, while at the same time the untoward reactions, such as circulatory disturbances, lowered metabolism, reduced defense mechanism, and depressed state of mind due to thyroid deficiency, would be attenuated to a considerable degree.

Idiopathic Thrombocytopenic Purpura.—The authors' studies of idiopathic thrombocytopenic purpura suggest an immunologic concept of the condition, although other humeral mechanisms, perhaps emanating from the spleen, cannot be ruled out. How or why platelet antibodies (agglutinins), destructive to the patient's own platelets, are evolved is at present unsolved. It is known that platelets and their products are antigenic. This is demonstrated not only by the development of platelet agglutinins by laboratory animals receiving heterologous platelets but also by the presence of antiplatelet agents in the plasma of thrombocytopenic patients receiving multiple platelet transfusions. It is conceivable that bacterial and viral agents and other noxious factors may modify the structure of the platelet and confer on it autoantigenic properties. It is also possible that the autoagglutinin might be the end-result of faulty synthesis of protein by diseased organs. Autoimmune thrombocytopenia may be just as real as autoimmune hemolytic anemia. With this in mind one can present a tentative classification of idiopathic thrombocytopenic purpura that is compatible with the better documented one for hemolytic anemia, by distinguishing between an intrinsic abnormality due to hereditary or acquired factors and an extrinsic disturbance of bacterial or viral, autoimmune, or hypersplenic origin. An immediate result of the authors' studies has been emphasis of the necessity for the careful assessment of the clinical and laboratory features of each case of idiopathic thrombocytopenic purpura with particular reference to its acute or chronic nature. This has considerable bearing on the decision whether and, if so, when splenectomy should be done. Splenectomy is at present the only available treatment for chronic idiopathic thrombocytopenic purpura and is successful in about 60% of the cases. The hazard of the splenectomy is negligible with the aid of corticotropin therapy and platelet transfusions. Less practical, but theoretically important, has been the development of the concept that each case of idiopathic thrombocytopenic purpura, whether acute or chronic, may well be an individual syndrome in which many different pathogenic mechanisms play an undetermined part.

Bacterial Resistance in Pulmonary Tuberculosis Treated with Isoniazid.—Since February, 1952, a clinical trial of isoniazid by the British Medical Research Council has been in progress with more than 1,300 patients receiving treatment in 53 hospitals. As part of this therapeutic trial the development of bacterial resistance over a period of six months to isoniazid and to streptomycin was studied in three groups of patients; 264 patients were given isoniazid alone, 233 received streptomycin combined with *p*-aminosalicylic acid, and 130 streptomycin combined with isoniazid. The standard doses of the three drugs were: 100 mg. of isoniazid twice a day, 1 gm. of streptomycin daily, and 5 gm. of the sodium salt of *p*-aminosalicylic acid four times daily. After three months of treatment, only a proportion of patients continued with the original chemotherapy; for those who continued, the dose of streptomycin was reduced to 1 gm. 2 or 3 times a week. Treatment was determined by random allocation, and the clinical condition on admission of the three groups of patients was comparable. Bacillary resistance to isoniazid was observed in 64% of 132 positive cultures, representing 35% of the total number of patients on whom cultures were made. At six months 30 positive cultures were obtained from 48 patients, and 28 of the 30 cultures (93%) were resistant. The development of isoniazid resistance in patients treated with streptomycin combined with isoniazid was in clear contrast to that in patients treated with isoniazid alone, since by three months of treatment 11% of 28 positive cultures were resistant, and resistant strains had been isolated from 2% of all patients treated with streptomycin combined with isoniazid as compared with 64% and 35%, respectively, for patients treated with isoniazid alone. At six months of treatment two of only four positive cultures (50%) were resistant, and these two resistant strains were obtained from a total of 58 patients for whom cultures were made (3%). For three months after treatment with isoniazid was discontinued there was no evidence of any general reversion of isoniazid-resistant strains either to a lower level of resistance or to sensitivity. For six months, streptomycin combined with isoniazid was as effective as streptomycin combined with *p*-aminosalicylic acid in preventing the emergence of strains resistant to streptomycin. On streptomycin combined with isoniazid 8% of positive cultures were streptomycin-resistant at three months and none of four at six months; on streptomycin combined with *p*-aminosalicylic acid the corresponding figures were 6% and 29% (two of seven). Patients with organisms initially resistant to *p*-aminosalicylic acid were not protected from the risk of development of streptomycin resistance by treatment with streptomycin combined with *p*-aminosalicylic acid.

*Sleep Therapy in Poliomyelitis; Attempted Prophylaxis of Paralysis with Sedatives. T. Brehme and W. Leuterer.—p. 751.

Sleep Therapy in Poliomyelitis.—Brehme and Leuterer emphasize the great importance of rest at the time of the first signs arousing suspicion of poliomyelitis or the first definite symptoms of the disease to prevent severe histochemical alterations, such as chromatolysis and loss of proteins and ribose nucleotides in the physiologically active ganglion cells. The destructive effect of the poliomyelitis virus is much more deleterious in the active, stimulated or fatigued cell than to the ganglion cell at rest. Strict rest in bed, particularly in the preparalytic stage, is imperative and should be made more effective by the administration of sedatives. Of 55 children with the premonitory meningitic signs and with positive findings in the cerebrospinal fluid and of additional 10 patients with adynamia, mild disturbances of innervation or reflex disturbances but with maintained motility, 39 received sleep therapy and 26 did not. The depth of sleep was so regulated that the children always could be awakened. The children were kept in a quiet, dark room. Transition from preparalysis to paralysis occurred in 4 of the 39 treated and in 5 of 26 untreated patients, a ratio of one-fifth in the untreated as compared to one-ninth in the treated. Because of the small number of cases this difference may not be statistically significant, but it has at least a certain "probability value." With respect to the course of the paralysis during the acute phase, 4 of 24 untreated children were improved, 13 were unchanged, and 7 became worse; 9 of 23 treated children were improved, 12 were unchanged, and 2 became worse. Control therapeutic trials by many observers on large alternating numbers of patients are suggested.

Radiological Aspects of Pulmonary Tuberculous Lesions Treated with Streptomycin.—Radiological examination is a reliable guide to the use of streptomycin in several forms of pulmonary tuberculosis, but not in all. Radiographs sometimes show improvement in apical and cavitary lesions, while cultures remain positive. Therapeutic indications in such cases are hard to determine, and the increased well-being of the patient makes him reluctant to submit to collapse therapy. In two of the author's patients, however, cultures that had been persistently positive after streptomycin therapy in spite of apparently normal lung pictures promptly became negative when a pneumothorax was instituted. Bacteriological examination thus becomes of paramount importance in evaluating the effects of treatment in patients showing radiological improvement after the administration of streptomycin. Similar problems are apt to arise in connection with the use of other antibiotics. Permanent closure of cavities is sometimes, though rarely, secured by antibiotic therapy. Elderly patients and those in poor general condition (e. g., alcoholics) for whom surgical treatment may be dangerous should, therefore, be given streptomycin, the efficacy of which is not reduced by advanced age or chronic alcoholism provided the cavities are not unduly old or large.

Radioactive Gold in Malignant Effusions.—Walter records his experience in attempting to control the reaccumulation of malignant exudates in the abdominal and thoracic cavities by radioactive gold. The radioactive gold, Au^{198}, is used in the colloidal form. The administration was by means of funnel and tubing. After the injection, the wound is sealed with collodion and gauze, and the patient is rotated, first on one side, then on the other, then head down, and then on his face, so as to distribute the radioactive fluid as uniformly as possible throughout the cavity. These turning maneuvers are continued at intervals in the ward for the next two hours. Later on the same day, a physical survey of the patient is made, with a Geiger counter, and the distribution of radioactivity is charted. There is always the possibility of finding a "hot-spot" due to loculated fluid that might lead to dangerously high local dosage; in this case, it might be judged advisable to withdraw radioactive fluid. Only one case has given anxiety in this way, but a repeat survey half a day later showed that the distribution had evened itself. Radiation reactions were mild. In 6 of 16 intraperitoneal injections, some abdominal pain with vomiting or diarrhea developed. Of four patients receiving intrathoracic injections, one had some pain. These reactions were never severe. In 8 of 15 patients who received the radioactive gold intraperitoneally no worth-while clinical effect was obtained, and 5 died within a short time. In four of the eight, considerable masses were palpable in pelvis or abdomen; it seems logical to expect poor results from a superficial form of treatment in such cases. In the seven cases in which a measure of success was achieved, reaccumulation of fluid has been controlled for periods of from 2 to 13 months so far. Control was achieved in only one of the four thoracic cases. The author suggests that radioactive gold might be used prophylactically in cases in which malignant cells are accidentally spilled at operation, as in cases of rupture of an ovarian cyst. Radioactive gold instilled intraperitoneally at the end of operation, or soon after, might have a decisive effect in eliminating early seedlings. He observed a case in which a little pseudomyxomatous jelly was found in the pouch of Douglas; 135 mc. of radioactive gold were instilled, and there has been no clinical recurrence for nearly two years.

Pneumoconiosis: I. Clinical Study in Relation to Functional Examination of Respiratory Tract; II. Experimental Pathology of Pneumoconiosis; and III. Pretended Protective Action of Aluminium in Preventing Pulmonary Silicosis. E. A. Pedace, A. E. Bachmann and M. S. Dreyer.—p. 89.

*Lack of Deferent Ducts: Four Cases. A. Trabucco and E. B. Bottini. —p. 118.

Lack of Deferent Ducts.—Of 400 men with azoospermia, 4 (1%) were found to have a congenital lack of the deferent ducts. These men were between the ages of 31 and 42 and complained of conjugal sterility. Together with total lack of deferent ducts, there was a total or a partial lack of the epididymis and, frequently, absence of the seminal vesicles. The posterior urethra and the verumontanum were normal. The diagnosis was suggested by a total azoospermia in the presence of normal size testes. The spermatogenesis is normal, as shown by a biopsy. There is no epididymis. The amount of semen eliminated varies between 0.5 and 1.5 cc. The diagnosis is verified by surgery. The four cases of this report are the only ones in the literature in which the abnormality was discovered while attempting to cure conjugal sterility of the patients. In the cases reported in the literature, the frequency of the abnormality is 0.5%, and the abnormality was observed during attempts of ligation of the deferent ducts for the purpose of either sterilizing the patients or preventing epididymal infection after endoscopic prostatectomy.

Some Actual Problems of Accident Medicine in the Field of Ophthalmology, Based on Experiences of the Swiss Accident Insurance Institute. F. Lang and J. Schürmann.—p. 667.

*Tuberculosis of Tonsils and Tuberculous Lymphoma of Neck. G. E. Stiefel.—p. 671.

*Experimental Contribution to Thrombin Therapy of Acute Gastric Hemorrhage. C. Usteri, M. Matter and F. Koller.—p. 674.

Tuberculosis of Tonsils.—Between 1941 and 1950, the tonsils were removed from 9,294 patients admitted to the Canton Hospital in St. Gallen, Switzerland. Microscopic examination of the removed specimens revealed unilateral or bilateral tuberculosis of the palatine tonsils in 240 patients, tuberculosis of the pharyngeal tonsils in 5, and tuberculosis of all three tonsils in 8, a total incidence of 253 (2.74%). In 410 of the 9,294 patients, clinical signs of unilateral or bilateral tuberculosis of the lymph nodes of the neck were observed at the time of the tonsillectomy, and three additional patients had open pulmonary tuberculosis. In these three and in 145 of the 410 patients, at least one of the tonsils was affected by tuberculosis. In the remaining 8,881 patients, tuberculosis was observed by chance in 105. Thus of the 253 (148 + 105) patients tuberculosis of tonsils occurred in three-fifths of patients with cervical lymphoma and in two-fifths of the patients without any clinical sign of tuberculosis. Routine examination of all removed tonsils for tuberculosis is suggested by these impressive data. Of the 253 patients with tuberculosis of the tonsils, 100 (39.2%) were males and 153 (60.8%) were females. The average age of the male patients was 15 years, and of the female patients 20 years. Of 117 patients with tuberculosis of the tonsils to whom a questionnaire could be sent 5 to 10 years after their tonsillectomies, an answer was received from 107. Eight (7.5%) of these 107 had tuberculosis. Exacerbation of the tuberculosis did not occur after the tonsillectomy in any of the patients. Sixty-six of the 107 patients had a cervical lymphoma at the time of the tonsillectomy, and in 18 a cure was obtained without any treatment in addition to tonsillectomy. In the remaining patients puncture or excision of the lymphoma was required, and in some the pharyngeal tonsils, which had been likewise infected by tuberculosis and had not been removed, acted as foci of dissemination. High altitude or sanatorium treatment before or after the tonsillectomy did not have any significant effect on the tendency to recovery in the patients with cervical lymphoma. Radical removal of the palatine, and if possible also of the pharyngeal tonsils, is indicated as a first step in the treatment of cervical lymphoma. Excision of the lymph nodes is necessary only in those patients who do not show any or only unsatisfactory tendency to regression. In patients with uncomplicated tuberculosis of the tonsils, high altitude treatment after tonsillectomy is not necessary.

Thrombin Therapy for Acute Gastric Hemorrhage.—To study the conditions of blood coagulation in the gastric juice of man, first a sample of gastric juice was examined which had been obtained by fractionated removal with a tube of the gastric contents from the stomach of patients in whom this procedure was carried out for diagnostic purposes. The same patients then were given a 2.5% Topostasin solution (5 gm. in 200 cc. of water), while the stomach tube was left in place. Topostasin is a proprietary preparation of dried thrombin obtained from cattle plasma with an addition of a phosphate buffer mixture and gelatin. Five grams of this preparation correspond to 1,500 NIH units of thrombin. The Topostasin containing gastric juice then was removed by tube 5, 10, and up to 60 minutes after the administration of the Topostasin solution. The coagulation activity of these various samples of gastric juice was tested by the addition of 0.2 cc. of a 500 mg. per 100 cc. of fibrinogen solution. In additional experiments the pH was determined by colorimetric method in other samples of the Topostasin containing gastric juice. Blood was aspirated with a graduated syringe from a vein of the patient's upper extremity and added to the various samples of the gastric juice. After mixing of blood and gastric juice the coagulation time was determined. In a control experiment the coagulation time was determined in a mixture of 0.5 cc. of sodium chloride solution and 0.5 cc. of blood. In a final series of experiments the blood coagulation in the gastric juice was determined before and after the oral administration of phosphate buffer mixture, the Topostasin solution, and milk. Results showed that blood coagulation is considerably delayed or even impossible in gastric juice of normal acidity and particularly of hyperacidity associated with ulcer. By ingestion of milk or phosphate buffer the pH of the gastric juice is shifted towards the neutral point, and thus the blood coagulation is favored. Blood coagulation occurs most rapidly if thrombin combined with phosphate buffer (in the form of Topostasin) is administered. The effect of the thrombin-phosphate buffer mixture on coagulation continues up to one hour. Repeated ingestion of this mixture (alternating with milk) is most effective for blood coagulation and, therefore, hemostasis in acute gastric hemorrhage.

BOOK REVIEWS

Ophthalmologic Diagnosis. By F. Herbert Haessler, M.D., Professor of Division of Ophthalmology, Marquette University School of Medicine, Milwaukee. Cloth. $8. Pp. 387, with 151 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

This new work presents a unique approach to ocular diagnosis. It could not serve as the sole textbook for an undergraduate student, since treatment is ignored, but, for the postgraduate student or resident in ophthalmology, there is served in palatable form a well-written and most informative treatise on the art of diagnosis, with many suggestions that should prove invaluable. Unlike most modern textbooks, it has no photographs or classical illustrations and has only a few diagrammatic drawings. In no sense a catalog of all known ophthalmological diseases, it is truly a "clear and concise road map to ophthalmology." In masterful fashion the author presents a philosophy of diagnosis that should be entertaining and instructive to the trained ophthalmologist as well as to the novice. The first few chapters contain a rather brief survey of fundamental principles that are elaborated on in subsequent chapters. The advantage of dividing the material in this manner is debatable, since it makes for some repetition. There has been, however, no casual compilation of chapters; there was a carefully considered plan. The material is accurate, and the volume can be highly recommended to anyone concerned with ophthalmologic diagnosis.

Natural History of Infectious Disease. By Sir Macfarlane Burnet, M.D., F.R.S., Director of Walter and Eliza Hall Institute, Melbourne. Second edition. Cloth. $4.50. Pp. 356, with 13 illustrations. Cambridge University Press, 32 E. 57th St., New York 22; Bentley House, 200 Euston Rd., London, N.W.1, 1953.

In this edition, the author recognizes and recounts the revolution that has occurred in the problems of infectious disease since the book was first written 20 years ago. The material presented is divided into five general parts. The first part deals with biological considerations, the second with the infecting microbes, and the third with defense mechanisms, including the chemical as well as the cellular basis for immunity. The fourth section considers the epidemiological factors, including the control of infectious disease, and the fifth section is concerned with some of the important infectious diseases. This is truly a remarkable book of its kind. The author has the ability to present complex subject matter with refreshing simplicity. Although this is not a reference or a textbook, any student who is beginning a course in bacteriology would do well to read it, and anyone who is interested in infectious diseases will find it valuable.

Ballistocardiography: The Application of the Direct Ballistocardiograph to Clinical Medicine. By William Dock, B.S., M.D., F.A.C.P., Professor of Medicine, State University Medical Center at New York City, Harry Mandelbaum, M.D., F.A.C.P., Associate in Medicine, Jewish Hospital of Brooklyn, Brooklyn, N. Y., and Robert A. Mandelbaum, B.A., M.D., Assistant in Medicine, Jewish Hospital of Brooklyn. Cloth. $9.50. Pp. 293, with 153 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

This concisely written monograph on ballistocardiography by a group that has pioneered the use of a simple, velocity-type, portable ballistocardiograph is most welcome, because there is still considerable controversy and confusion on this subject. Since 1948, the authors have made numerous ballistocardiograms on normal and abnormal subjects under a variety of different circumstances. They have accumulated sufficient data to make possible some general statements on the value of the ballistocardiogram in diagnosis and prognosis. In interpreting the ballistocardiogram, the authors indicate the necessity of considering the ballistocardiogram as only part of a medical examination. The following quotation from page 103 points out the fallacy of making a diagnosis from the ballistocardiogram alone: "Trivial and transient disturbances of the circulation may produce abnormal tracings; severe heart disease, especially when diastolic pressure is low, may be present with normal tracings of low amplitude. If an expert, on the basis of tracings alone, even hints that the myocardium is diseased or is healthy, he is not helping the physician who refers the case and he may be harming the patient."

No previous knowledge of the subject is assumed, so the entire field of ballistocardiography is covered, from a discussion of physical and physiological principles to its application in disease. There is also a chapter relating the results of the authors' investigations on the effect of smoking on the ballistocardiogram. Many excellent illustrations supplement a well-written text. This is one of the best monographs so far published on ballistocardiography. It should be an extremely useful reference book not only for the cardiologist but for any physician who has the desire to learn about this new and interesting diagnostic aid.

The Action of Insulin. By Niels Haugaard, Ph.D., Assistant Professor of Physiological Chemistry in Research Medicine, School of Medicine, University of Pennsylvania, Philadelphia, and Julian B. Marsh, M.D., Assistant Professor of Physiological Chemistry, Graduate School of Medicine, University of Pennsylvania. Publication number 194, American Lecture Series, monograph in American Lectures in Endocrinology, edited by Willard O. Thompson, M.D., Clinical Professor of Medicine, University of Illinois College of Medicine, Chicago. Cloth. $3.75. Pp. 113, with 8 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This new monograph with an introductory chapter by Dr. William C. Stadie presents an excellent summary of the problematic concepts and known facts regarding the properties and action of insulin. The nature and probable pathways of intermediary metabolic reactions that are involved are concisely reviewed along with the chemistry of the hormone and its physiological action. The relationships encountered in experimental diabetes and the influence of other hormones on the action of insulin are carefully outlined. Certain speculative clinical aspects of its action are included. The final chapter deals with a discussion of what is known and what is unknown concerning the biochemical mechanism of insulin action on cellular metabolism. Each chapter except the first is followed by a list of references, which are annotated in the text. A general index is placed at the end. The printing and flexible binding are appropriate for a book of monograph size. No typographic errors were found. The book will be useful to all advanced students and investigators interested in the action of hormones in general and that of insulin in particular.

Elsevier's Encyclopædia of Organic Chemistry. Series III: Carboisocyclic Condensed Compounds. Volume 12B: Naphthalene. A. Compounds Containing One Naphthalene Nucleus: Carboxylic Acids (CO_2H in Side Chain). Founded by E. Josephy & F. Radt. Edited by F. Radt. Cloth. $66; $58 to series subscribers; $50 to set subscribers. Pp. 3261-3963. Elsevier Press, Inc., 402 Lovett Blvd., Houston 6; 155 E. 82nd St., New York 28; 118 Spuistraat, Amsterdam C, Netherlands; Cleaver-Hume Press, Ltd., 42A S. Audley St., London, W.1, 1953.

This volume in this extensive and important chemical series covers the carboxylic acids that contain the naphthalene skeleton. Such better-known compounds as the naphthylacetic acids, santonin, carboxylic acid derivatives of decalin, and tetralone are included in a host of organic compounds that are lesser known (to the physician). Wherever possible, data are given concerning the physiological and biological properties of these substances. The literature through 1944 and the structure of compounds as determined up to the beginning of 1953 are included.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

Diseases of the Digestive System. Edited by Sidney A. Portis, B.S., M.D., F.A.C.P., Associate Clinical Professor of Medicine, University of Illinois Medical School, Chicago. Third edition. Cloth. $20. Pp. 1119, with 274 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1953.

Knowledge of the digestive tract and its functional and organic disorders has advanced greatly in the last decade. Refined methods of study have clarified much of the darkness that surrounded the physiology and pathology of the system. An appraisal of the various disorders arising in the digestive canal requires a review of a vast amount of important literature that reflects the opinions of a large body of experienced observers.

This edition contains the contributions of 57 acknowledged authorities and reflects the increasing emphasis given to psychodynamics and the psychogenesis of gastrointestinal disorders. The order of the book follows a logical progression. Following a historical review, charts on the anatomy and physiology of the digestive system include recent advances in the dynamics of digestion. Particularly worthy are the discussions on the neurological aspects and consideration of the emotional factors that underlie the majority of everyday digestive complaints. Chapters on allergy, the anemias, and a résumé of dietetic concepts represent modern interpretations. After a well-documented section on roentgenology, chapters on the disorders of the various parts of the system, from the mouth to the anus, are presented by recognized authorities. The chapter on peptic ulcer by Palmer is especially noteworthy because of its broad, yet detailed, consideration of this disorder of modern civilization. The discussion of diseases of the extrahepatic biliary passages and the one on diseases of the liver by Portis stand high in the current literature regarding the gastrointestinal tract.

The last seven chapters deal with gastrointestinal manifestations of other diseases, including arthritis, with disorders of the endocrine system and the relationship between the gastrointestinal and cardiovascular systems. Two chapters by Leiter on alkalosis and renal disease are excellent. This volume has only a brief reference to esophageal varices, a condition that is appearing with distressing frequency. The clinical picture of a bleeding varix may baffle the attending physician as a diagnostic challenge, and the difficulty of finding an adequate solution for the control of bleeding may distress him even more.

There can never be any substitute for a careful and logical record of the patient's disorder. The trend in teaching today tends to emphasize technical procedures with insufficient attention to the patient as a whole. A chapter on the art of taking a history and the technique of carrying out a physical examination would be a helpful addition to this book. This edition, edited by Portis, is a classic. The interests of the patient will be greatly served and much time will be saved for the specialist, the general practitioner, and the student if they have within easy reach a copy of this superb presentation.

British Pharmacopœia 1953. Published under direction of General Medical Council pursuant to Medical Council Act 1862 and Medical Act 1950. Official from 1 September 1953. [Eighth edition]. Cloth. 50s. Pp. 894, with 12 illustrations. Published for General Medical Council by Pharmaceutical Press, 17 Bloomsbury Sq., London, W.C.1, [1953].

The latest edition of the British Pharmacopeia, which became official Sept. 1, 1953, is unquestionably an improvement over previous editions. For the first time English has been substituted for Latin in the main titles of the monographs. The various dosage forms of a basic drug are all listed in sequence. Thus tablets of digoxin appear immediately after digoxin instead of being grouped with all other tablets of official substances. Usual doses are given in metric units, with the apothecary equivalents indicated only for older drugs. The 150 deletions are composed largely of botanicals that are difficult to standardize and have been largely supplanted by other newer drugs. Ergot has been deleted, but ergometrine maleate and ergotamine tartrate have been added. Other deletions involve agents that have been replaced by less dangerous drugs. There is a total of 62 newly admitted substances.

Less striking on casual inspection, but significant, are the changes in monographs for substances in the 1948 edition. For instance, assays have been added in many cases. Molecular weights were recalculated from the 1951 Atomic Weight Table. The appendix on biological assays and tests presents the biometrical principles of assay, with descriptions of the designs of assay for various official substances. In the introductory section there is a list comparing the titles of monographs in the B. P. and the titles for the corresponding drugs in the International Pharmacopeia, first edition, volume 1.

Differential Diagnosis of Common Diseases of the Eyeground. By Paul Tower, M.D. Cloth. $10. Pp. 243, with 129 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

This book consists primarily of an atlas of fundus photographs, with accompanying chapters elaborating on the differential diagnosis of various changes in the fundus oculi and some discussion of the literature dealing with these changes. The illustrations are black and white, and therefore frequently fail to convey to the inexperienced or beginning ophthalmologist an accurate concept of the true appearance of the pathological fundus. The text is for the most part satisfactory, and the illustrations are adequate in number. To one with some training in ophthalmoscopy, the book should prove useful.

Encyclopedia of Chemical Technology. Volume 10: Pentacene to Polymethine Dyes. Edited by Raymond E. Kirk, Head, Department of Chemistry, Polytechnic Institute of Brooklyn, Brooklyn, N. Y., and Donald F. Othmer, Head, Department of Chemical Engineering, Polytechnic Institute of Brooklyn. Assistant editors: Janet D. Scott and Anthony Standen. Cloth. Subscr. price, $25 per volume. Pp. 976, with illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; 2a Southampton Row, London, W.C.1, 1953.

THE JOURNAL reviews of the first nine volumes have indicated the interest that this encyclopedia holds for physicians, although it is primarily concerned with chemical technology. The articles, even of the most technical nature, are clearly but briefly expressed. Of particular interest to the physician are discussions on perfumes, peroxides, petroleum (composition, origin, refinery processes, products, chemicals, and waxes), pharmaceuticals (product forms, research, process development, manufacturing, control, and new product development) phenols, phenolic resins and plastics, phenolphthalein, phenylenediamines, phosgene, phosphorus and phosphorous compounds, photochemistry, photoelectric cells, photography, inorganic and organic pigments, plant growth substances, plasma expanders, plasticizers, plywood, economic poisons, polyethylene, and polymers. Many other subjects are presented that may not be of such general interest to the physician, but, if he wishes to know something about allied technical fields, there is no better reference source than this encyclopedia.

Die Wissenschaft vom Traum: Ergebnisse und Probleme. Eine Einführung in die allgemeinen Grundlagen. Von W. v. Siebenthal. Mit einem Vorwort von Victor Emil Freiherr von Gebsattel. Cloth. 39.60 marks. Pp. 523, with 3 illustrations. Springer-Verlag, Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1953.

Extremely well written, and fortified with 1,309 references to previous publications, this book summarizes almost everything of interest that has been written about dreams from the time of Joseph and the Pharaohs to Freud and Jung. Concerned with dreams as manifesting the experiences and aspirations of the dreamer, it should be useful in libraries devoted to psychoanalysis. The word *Wissenschaft* in the title, however, invites evaluation of the book as a work of science. In 10 lines on page 151 the author dismisses statistical methods as having limited value. Kinsey and others who have contributed substantially to the important literature on nocturnal emissions are not mentioned, and, in general, the space given to the data of experimental and physiological psychology is scanty. This book exemplifies the "preoccupation with superficially acceptable conclusions" pointed out recently by Altschule as the bane of psychiatry, and it places the present work low on the scale of scientific writing. As Altschule says, "A thoroughly sound psychiatry cannot develop until all men working in it take for granted that accumulation of valid data is of primary importance."

Histochemistry: Theoretical and Applied. By A. G. Everson Pearse, M.A., M.D., D.C.P. Cloth. $12. Pp. 530, with 113 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., London, W.1, 1953.

Pathologists and other scientists who study animal tissues will be pleased with this book. It is the first important work in its field since 1949; it is logically organized, beautifully written and printed, well illustrated, and thoroughly indexed.

In the preface, the author states that the book "deals solely . . . with theoretical and practical aspects of microscopical histochemistry. I decided, at the outset, to practice all the available methods in the various fields and to modify or reject those which proved useless. . . . For each method I have provided full theoretical details and sufficient critical comments to make clear its essential purpose and range of usefulness. . . . For the methods themselves . . . [there are] technical appendices to each chapter so that the whole appendix forms a complete . . . unit." A sketch of the historical development of histochemistry from 1800 to 1952, a discussion of the chemistry of tissue fixation, and a chapter on freeze-drying technique are included. Several chapters are concerned with the identification in body tissues of such chemical constituents as proteins, nucleoproteins and amino acids, carbohydrates, lipids and lipoproteins, aldehydes and ketones, pigments, and certain inorganic constituents. Five chapters are devoted to the identification of enzymes and enzyme substrates, and a final chapter deals with physical methods of determination of tissue components. The appendix, containing directions for performing the various tests, is 80 pages long. The book can be highly recommended as a text for medical students.

The Normal Child: Some Problems of the First Three Years and Their Treatment. By Ronald S. Illingworth, M.D., F.R.C.P., D.P.H., Professor of Child Health, University of Sheffield, England. Cloth. $6. Pp. 342, with 64 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., London, W.1, 1953.

This book is written by an English author with considerable background of practical experience of child study and child care in the United States as well as England. The purpose of the text is to describe the physical and developmental variations that may occur in the normally progressing child. The author stresses the importance of recognizing the considerable latitude of normalcy and the need to recognize the boundary between this and disease. There is no discussion of disease conditions of this age period.

The book is divided into four sections covering problems of feeding, of physical and developmental growth, and of behavior. The section on breast feeding is particularly thorough, with consideration of the many problems incident to initiating and maintaining this desirable method of infant feeding. Perhaps the most valuable portion of the book for factual reference is in the sections on the phases of development, where the influence of the author's association with Gesell is strongly apparent. Less extensive coverage is given the numerous disturbing but normally encountered behavior problems that are to be expected in the process of growing up. Frequent references from an extensive bibliography are included, along with treatment recommendations based on the author's own considerable practical experience. This book appears particularly useful as a handy reference on developmental appraisal and minor problems for those concerned with children of this early age period.

Nursing of Children. By Gladys Sellew, B.S., R.N., Ph.D., Professor and Chairman of Department of Sociology and Social Work, Rosary College, River Forest, Illinois, and Mary F. Pepper, A.B., R.N., M.S.N.E., Educational Director, Christ Child Home for Convalescent Children, Washington, D. C. Seventh edition. Cloth. $3.75. Pp. 349, with 60 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

The sixth edition of this work has been completely rewritten with a view to providing a different approach in the presentation of material. Where, formerly, material was arranged according to diseases affecting each body system, this book introduces pediatric nursing with a study of the normal growth and development of the child, followed by a discussion of the diseases common to different age groups through adolescence. This approach facilitates the adaptation of nursing care to the need of patient. Part 1, "Social Psychology of Childhood," includes chapters on the history of pediatric nursing, the child in the family and the community, and normal growth and development during the periods from infancy through adolescence, and part 2, "Illness in Infancy and Childhood," deals with general pediatric nursing procedures as well as patient care in specific diseases. Chapters are included on recreation and the nurse's role in the admission of a child to the hospital. Lists of references are given for the various sections.

This new approach to the subject of pediatric nursing is an excellent means of orientation, because it deals in fundamentals. Although the subjects in this small book are not discussed in great detail, a pattern is set in which all aspects of pediatric nursing are viewed in their proper perspective. It should be a particularly effective introductory text for students in pediatric nursing.

Effective Use of Older Workers. By Elizabeth Llewellyn Breckinridge, Executive Secretary, Illinois Committee on Aging. Foreword by Edward L. Ryerson, Chairman, Inland Steel Company, Chicago. With special contributions by Elizabeth Hatch, Curtis Gallenbeck, L. S. Barrus, and John Bromer. Cloth. $4. Pp. 224. Wilcox and Follett Co., 1255 S. Wabash, Chicago 5, 1953.

This book reports the findings of a national survey of corporate practice and thinking relating to the better use of our aging work force. The study was directed by Elizabeth L. Breckinridge under the supervision of the Committee on Human Development at the University of Chicago and was financed by a grant from the Rockefeller Foundation. The purpose of the survey was "to explore (1) the way in which some companies were using older workers more effectively than the average employer and (2) the procedures being devised to facilitate retirement and subsequent adjustment." Ninety companies, ranging from great corporations like General Motors and Standard Oil down to small shop operations, cooperated in supplying the information contained in this book. The author has arranged her material into a clear and pleasant narrative dealing successively with hiring, retiring, placement, counseling, maintenance of health and morale, preparation for retirement, and postretirement programs.

Throughout the report, the integral and significant role of the company medical officer is referred to again and again. His relationship to other departments of the company in building a program for older employees and pensioners is thoughtfully considered. In the section discussing health maintenance for the aging worker it is clear that we are merely at the beginning of a new attitude toward the older worker. Corporations are feeling their way and experimenting with pilot plant operations in this field. Nevertheless, from the data available, the author has been able to formulate some basic principles for programing company health services for this group of workers. Other attractive features of this report include several contributed papers from industrial relations executives and a good selected bibliography for those wishing additional information. This book is recommended reading for those interested in industrial medical programs, personnel work, and industrial relations.

Mechanisms of Urologic Disease. By David M. Davis, M.D. Cloth. $4.50. Pp. 156, with 6 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

This readable little volume gives a bird's-eye view of urologic problems with emphasis on the physiological processes and pathological changes involved. In contrast to most treatises on urology, instead of dividing the subjects on an anatomic basis, the author appropriately treats the subjects on the basis of eight different types of pathological changes. In emphasizing physiological and pathological features, he stresses the results of obstruction in the urinary tract. In fact, the chapter on obstruction is the most valuable contribution in the book.

Whether or not the results of obstruction are as influential in involving all of the various diseases in the urinary tract as the author claims might be open to question, but the importance of obstruction in the field of urodynamics is quite evident, and his treatment of the subject is very interesting. Although the subsequent chapters are too brief for serious consideration, they offer a fair review of the subjects involved. The list of references, while adequate for the purpose, is somewhat insular and includes only comparatively recent references on the various subjects discussed. Although the treatise is meant chiefly for "beginners and for those physicians who are not urologic specialists," every urologist will find it interesting reading.

Slipped Capital Femoral Epiphysis. By Armin Klein, M.D., Robert J. Joplin, M.D., John A. Reidy, M.D., and Joseph Hanelin, M.D. Publication number 153, American Lecture Series, monograph in American Lectures in Roentgen Diagnosis. Edited by Aubrey O. Hampton, M.D., Chief, Department of Radiology, Garfield Memorial Hospital, Washington, D. C. Cloth. $6.75. Pp. 130, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, 1953.

The arrangement of the material in this well-written monograph is such that each phase of this problem can be adequately followed. The series of roentgenograms of normal hips, taken in both anteroposterior and lateral projections on boys and girls, should be an extremely valuable reference. Nowhere else has such a series of hip films been compiled. The method of treatment of these hips, of internal fixation and active mobilization, is highly recommended. The results recorded by the authors are somewhat better than many others report, but this is probably due to the fact that they have used the criteria for treatment outlined in this book. It is of further interest that the number of cases of bilateral hip involvement has increased as a more critical evaluation of both hips has been given. The reported 40% bilateral involvement is higher than most previous authors report but is probably still short of the actual prevalence. This is an excellent reference book and should be of great value in comparing a slipped capital femoral epiphysis with the normal hip.

Age and Achievement. By Harvey C. Lehman. Memoirs of American Philosophical Society held at Philadelphia for promoting useful knowledge, volume 33. Cloth. $7.50. Pp. 359, with 170 illustrations. Princeton University Press, Princeton, N. J., 1953.

In this notable and interesting book, a product of 20 years of careful research, the author explores the relationship between chronological age and the quality and quantity of achievement and establishes, for many fields of endeavor, the age level at which man's most creative work has been done. These cover such diverse fields as medicine, music, literature, art, philosophy, mathematics, business, statecraft, and athletic prowess. In general, an attempt has been made to assemble the best basic data on the subject of age and achievement that it has been possible to collect, and an incredible amount of factual information is presented in readily understood graphs and tables. Whatever else this book may reveal, it suggests that outstanding intellectual achievement depends far less on mere length of life or on the number of years a particular person has been working within a given field than might have been supposed. The data presented in this important book are so challenging in their implications as to exert presumably far-reaching effects on established patterns of thought in psychology and in education.

School Nursing in the Community Program. By Marie Swanson, R.N., M.A., School Nursing Consultant, Department of Public Health Nursing, National League for Nursing, New York. Cloth. $5. Pp. 543. The Macmillan Company, 60 Fifth Ave., New York 11, 1953.

"This book deals with the school child, his parents and teachers, the health department and other official and voluntary agencies, the community in which he lives and the nurse who works in his school. It portrays nursing as it is most effectively carried on in the schools today." Thus the author sets the stage for a detailed discussion of the nurse serving the school, the characteristics and relations of her position, and the community of interests within which she performs her services. The primary appeal of this volume is to nurses concerned in some way with a school nursing service. This book will probably have a marked influence on the development of school nursing in the future. It will be of secondary interest to the school administrator, the local health officer, and others responsible for the direction of nurses serving the school.

Though the nurse is the center of attention in this volume, the entire school health program is described and discussed as the setting for the nurse's services. This involves all of the persons concerned with child health in the school and the community and the cooperative relations between them and the school nurse in evolving a school health program. The five major subdivisions concern the community's part in the development and protection of children, the work of the nurse with school-age children, the nurse's part in individual pupil appraisal and assistance, the nurse's part in general health supervision and education, and work in special situations. A good index and a list of organizations and magazines make reference easier.

Cornell Conferences on Therapy. Volume Six. Edited by Harry Gold, M.D., et al. Cloth. $4. Pp. 287. The Macmillan Company, 60 Fifth Ave., New York 11, 1953.

This book presents a series of 15 conferences on therapy conducted at Cornell University Medical College by 57 participants. The conferences, each devoted to a single topic or theme, are divided into chapters presenting an edited record of the discussions and questions by the participants. The majority of the participants are members of the Cornell group, but authorities from other medical centers are also included. Some, but not all, of the conferences have already been published in the *American Journal of Medicine* or the *New York State Journal of Medicine*. A total of 76 similar conferences has also been published, partly in periodicals and partly in the five previous volumes of this book. The dialectic form of presentation is as interesting as it is instructive, and the present volume sustains the purpose of the conferences: to bring pharmacology and other essential basic knowledge into closer integration with clinical therapeutics. Sincere differences of opinion occasionally expressed reveal a critical approach to difficult problems.

Physicians in general and students of therapeutics in particular will welcome this new collection of the conferences in book form. A list of the conferences published in the preceding five volumes is included at the end. Lack of an index limits the usefulness of the book as a reference. A few minor errors occur that might have been avoided, for example, amphenicol for chloramphenicol on page 122. In some instances the use of brand in place of generic names for drugs is disappointing, e. g., Pentothal for thiopental on page 50.

Communicable Diseases: A Textbook for Nurses. By Albert G. Bower, M.D., F.A.C.P., Head of Department of Communicable Diseases, Los Angeles County General Hospital, Los Angeles, California, and Edith B. Pilant, R.N. Seventh edition. Cloth. $5.50. Pp. 640, with 83 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

This book has been completely rewritten in the present edition. All subjects previously covered are again included, and new material has been added. All common communicable diseases are discussed in terms of definition, etiology, pathology, incubation period, symptoms, treatment, and nursing care. Other aspects, such as differential diagnosis, immunity, and complications and sequelae, are discussed where pertinent. Early chapters are devoted to aseptic technique, care of communicable diseases in the home, and public health control of communicable disease. Each chapter is followed by a series of questions and a reference list. A glossary of medical terms is included at the end. This book will serve the student nurse as a textbook and the graduate nurse as a reference. The discussions of the various diseases are more complete than those found in many other textbooks for nurses.

QUERIES AND MINOR NOTES

HAY FEVER AND ASTHMA

To the Editor:—*1. What is the incidence of bronchial asthma as a sequel of hay fever and how can it be prevented? 2. Is the all year around method of desensitization better than preseasonal desensitization? 3. Where can one find escape from ragweed pollen in the central northeastern part of the United States? Are there any relatively pollen-free areas in Illinois, Ohio, Indiana, Michigan, or Wisconsin? 4. What are the criteria of using corticotropin or cortisone? Is corticotropin (ACTH) or the "gel" here more indicated than cortisone? 5. Does air conditioning in an isolated room afford relief? 6. Does the ingestion of alcohol aggravate the symptoms of hay fever?* *M.D. Ohio.*

Answer.—1. The exact incidence of bronchial asthma as a sequel of hay fever is not known, but the general feeling is that about 40% of patients with hay fever sooner or later develop bronchial asthma unless they receive injections of the specific extracts of the offending pollens, either trees, grasses or weeds. These injections, if given adequately and in time, will almost certainly prevent the onset of asthma in at least 95% of cases. Unfortunately, the results as regards hay fever are not quite as good. The injection method is almost certainly the only specific and valuable method of treatment other than avoidance.

2. In the experience of many, the perennial method of treatment is far better than the preseasonal. This is because the dosages can be gradually raised, and the patients can usually reach much higher amounts if the injections are given all year round than if they are hurried and crowded into three or four months preceding the hay fever season. Many patients delay reporting for their peseasonal treatment, and this results in a lack of protection because the dosage cannot be raised high enough. (There are a few allergists who insist that they get equally good results with minimal or very moderate dosages.) The perennial method is also better in that the percentage of reactions seems to be distinctly less than when treatment is hurried and the doses are increased too rapidly.

3. The amount of ragweed pollen is distinctly less in the northern parts of Wisconsin and Michigan, as well as in the central and northern parts of Canada. Ragweed is practically absent in the Gaspé Peninsula. Ragweed is abundant all through Illinois, Ohio, Indiana, and lower Michigan and Wisconsin. Ragweed is practically absent west of the Rocky Mountains and in Miami, Fla. Elevated areas like the White Mountains have less pollen than the valleys, but they are not free from ragweed. Ragweed hay fever does not exist in Europe or in other continents.

4. Corticotropin or cortisone usually does give excellent relief both for ragweed hay fever and ragweed asthma. However, in the majority of patients who receive the hyposensitization treatment, these hormones are not necessary as the hay fever symptoms can usually be controlled, if necessary, by antihistaminic drugs. The hormones are advised in some patients who have severe symptoms and who report after the hay fever season has already started. In such cases, the use of cortisone in tablet form will often give excellent and prompt relief. There are the well-known precautions, as they cannot be used in certain conditions, especially peptic ulcer, pulmonary tuberculosis, and psychosis. They must be used cautiously, if at all, in patients with high blood pressure and diabetes.

Cortisone by tablet is probably better for those who have ragweed hay fever; the ACTH-Gel, with or without cortisone, can be used for the ambulant patients who have asthma and hay fever. If asthma is violent enough for hospitalization, intravenous administration of corticotropin, 20 units in a liter of 5% dextrose in water, 3 liters a day—is advised. This can be given by the continuous drip method, and in each liter 0.5 gm. of aminophylline should be added. This method almost always gives excellent results.

5. Air conditioning affords relief for hay fever provided the patient stays in the room with the machine. Relief ceases when the patient leaves the room. Unfortunately, if the air conditioning causes too severe a drop in temperature, the patient who has a tendency for asthma is apt to have the same symptoms even though he is in the air conditioned room. Many therefore believe that air filters are better than air conditioning for patients who have asthma from pollen.

6. It is reasonable to assume that ingestion of alcohol, which is a vasodilator, may aggravate the symptoms of hay fever. The alcohol might open the nasal passages, which would then become more receptive to the aggravating effects of the pollen.

IMPOTENCE IN DIABETICS

To the Editor:—*Please discuss impotence, its mechanism, prognosis, and treatment in a young man with diabetes.*

Sal Citra, M.D., Bronx, N. Y.

Answer.—Impotence is not uncommon in nondiabetics. A specialist in this field writes, "Failure of erection or ejaculation in intact males under fifty is, I believe, always psychological, except in cases of asthenia from starvation or disease. In men over sixty such impotence is so common as to be considered normal; but even in such, I rather think it is often due basically to a psychological, not a truly hormonal, change." Obviously asthenia is common in diabetics, although neurasthenia and hypochrondria are less frequent, because the patients are concretely occupied with treatment.

The mechanism of impotence in diabetes could be due to pathological changes in the sexual glands, to alteration of the secretion of the pituitary gland, or to dysfunction of one or the other on account of the diabetic state. Against the latter cause is the fact that impotence occasionally accompanies the onset of diabetes, and against a pathological change is the fact that usually there is no obvious disease or deformity in the genital tract. The condition appears to be functional rather than organic. Against its being of neuritic origin is its usual permanence, whereas with diabetic neuritis, peripheral or otherwise, improvement is almost invariable. Further studies on the activity and production of the 17-ketosteroids in diabetics with and without potency might give new information about impotency in diabetes.

The incidence of impotence in diabetes is unknown, but it is a common symptom, even, according to writers such as Von Noorden and Isaac, reaching 53% in patients who attain a suitable age. Naunyn states that, in men with diabetes, impotence is one of the most constant symptoms. Yet it can be absent, and instead of it there may be temporarily an increased sexual desire; Von Noorden and Isaac noted the latter in only 1% of their patients. Impotence may be a premonitory symptom, but in such cases the actual date of onset of the disease is often problematical, because such early symptomatology applies to the middle-aged rather than to the young patient. It is not always the consequence of exhaustion or loss of sugar in the urine, since it occurs in well-nourished diabetics with very little excretion of sugar. Yet in only moderately severe cases, sexual capability sometimes returns when glycosuria disappears or decreases, but this is exceptional in severe cases. Atrophy of the testicles has been observed in young men. On the other hand, Griesinger observed patients in whom impotence may have been present in severe diabetes even though, at autopsy, there were abundant and actively moving sperma-

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

tozoa in the testes, thus showing that the impotency was not due to the destruction of spermatozoa. In hemochromatosis with diabetes, testicular atrophy affords a well-known anatomic basis for impotence.

Psychic factors, such as anxiety and fear of the future with respect to vision, arteriosclerosis, and gangrene, have special importance in diabetic patients. Anxiety, nerve tension, and depression are well-known factors for impotence among nondiabetics. They do not, however, seem adequate to explain the impotence seen with such frequency in young diabetic patients. Impotence in a man, however, is not invariable after 30 years of diabetes. The wife of one such man recently gave birth to their seventh child. Moreover, the wife of another man with diabetes of 34 years' duration gave birth to twins after 30 years and a seventh child after 33 years. The first man was carefully treated from onset although the second received unusual, but not such careful treatment.

The prognosis for relief of the impotence is dubious, but instances of recovery even after many years do occur. Whether these are due to psychiatric or medical therapy is uncertain. Treatment is unsatisfactory but testosterone in 25 mg. doses, injected twice weekly, has occasionally produced surprising results. This is especially true even in hemochromatosis in which atrophy of the testes is noted, together with marked diminution in the size of the prostate. The question remains, however, as to whether the improvement was due to improvement of the general physical condition or to actual relief of the impotence.

The effect of impotency on the patient psychologically far, far outweighs the physical harm. Failure to recognize the possibility of impotence and its later development undoubtedly wreck many marriages. A man will put up with the illness of his wife "for better or worse," but a woman is not inclined to overlook impotency when it develops in her husband, even though there have been children and middle life has been reached.

STERILE ABSCESS FOLLOWING IMMUNIZATION

To the Editor:—*During 15 years of pediatric practice I have encountered an occasional child in whom a sterile abscess developed after an injection of a routine immunization. I now have a patient with a history of a sterile abscess following every routine immunization injection. What can be done to prevent its recurrence?*

D. L. Weinstein, M.D., Washington, D. C.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Abscess formation can usually be avoided if three precautions are taken. 1. Needles and syringes should be autoclaved; boiling for at least 10 minutes may be sufficient. 2. The skin should be cleansed and disinfected, and the stopper of antigen container should be given same treatment. 3. The outside of the needle should be clean, and 0.1 to 0.2 cc. of air should follow expulsion of the antigen; a sterile abscess may be due to outside coating of needle with alum. Although only the third precaution may apply to your requirements, the other two are sometimes neglected. As a last resort fluid toxoid may be substituted for alum precipitated toxoid.

Answer.—In both fluid and alum precipitated pertussis vaccine, local and general reactions may occur. The local reactions are indurated nodules at the site of the injection that occasionally cause a migration of leukocytes to the area resulting in fluctuation and a sterile abscess. This is due to pertussis bacillus protein and endotoxins, depending on individual tissue susceptibility. In a few instances, this may be due to insoluble alum acting as a tissue irritant. Severer reactions tend to develop in older children. The injections are best given intramuscularly or deep into the subcutaneous tissue. Care should be taken to avoid depositing the vaccine immediately beneath the skin, in the upper part of the subcutaneous layer of fat, or in sites that have received previous injections. The same is true of both fluid and alum precipitated diphtheria toxoid. The reactions are accounted for mostly by hypersensitiveness to diphtheria bacillus proteins of the toxoid preparations. This sensitization is acquired through contact with the diphtheria bacillus as the person becomes older, or it may develop through previous injections of toxoid. This again becomes more marked in older persons.

Local or systemic reactions may be observed after injections of either the plain tetanus toxoid or alum-precipitated toxoid. These as a rule are never so severe since the person is not so hypersensitive to the tetanus bacillus proteins as he may be to the diphtheria bacillus proteins, despite previous contact with the tetanus bacillus. This also applies to combined immunizations. Diphtheria immunization should be preceded by a Schick test and should be given only to those susceptible after a Moloney test for sensitivity is known to be negative; if the reaction to a Moloney test is positive, immunity may be acquired by giving smaller injections over a longer period of time.

METHODS FOR STAINING EOSINOPHILS

To the Editor:—*I have been using Randolph's staining solution, which should color eosinophilic granules red and those of other leukocytes blue. I have been using either equal amounts of the two solutions or four parts of solution 1 and six parts of solution 2, and I have observed a 21 hour waiting period. Yet, I cannot differentiate the colors. What proportions do you advise me to use? I have heard about Hinkleman's solution. Which do you consider the better of the two?*

Guzman Casanova, M.D., Encrucijada, Cuba.

Answer.—The following methods are satisfactory for determination of the absolute eosinophil count:

1. Dunger's method (described in *Blood* 3:755, 1948): With this method the eosinophils are stained vividly, but precise timing is required because of the dissolution of leukocyte membranes, and the method is, therefore, convenient only with venous blood.

2. Randolph's method (*J. Allergy* 15:89, 1944): While suitable for capillary or venous blood, this method is cumbersome and does not allow as clear a distinction between eosinophils and other leukocytes as do other methods.

3. Henneman's modification of Randolph's method (*J. Lab. & Clin. Med.* 34:1017, 1949): This method employs a diluting fluid made up of 0.05 gm. of phloxine, propylene glycol, and 50 ml. of distilled water, which simplifies Randolph's technique.

4. Hinkleman's method: The solution used (0.5 gm. of yellow eosin, 0.5 ml. of concentrated formaldehyde [Formalin], and distilled water to make a total volume of 100 ml.) stains eosinophilic granules black, while other than eosinophilic leukocytes appear as shadows. This method may be used on either capillary or venous blood.

5. Rud's method (*Acta psychiat et neurol.*, supp. 40, 1947): A solution composed of 0.1 ml. of 10% magdala red, 6 ml. of acetone, 14 to 20 drops of 10% sodium carbonate, and 45 ml. of water is used. While the staining obtained is excellent, the chamber must be filled promptly and evaporation prevented.

6. Pilot's method (*Am. J. Clin. Path.* 20:870, 1950): This method employs a solution consisting of 50 ml. of propylene glycol, 40 ml. of distilled water, 10 ml. of 1% phloxine in water, and 1 ml. of 10% sodium carbonate. This is suitable for capillary or venous blood, and counting chambers may be filled at leisure and the cells counted any time within 15 minutes.

7. Manner's method (*Brit. M. J.* 1:1429, 1951): A solution containing 50 gm. of urea, trisodium citrate, distilled water to make a total volume of 100 ml., and 5 ml. of a 2% aqueous solution of phloxine is employed.

While any of the above methods is satisfactory, the last two are preferred, since they may be used on either capillary or venous blood, other leukocytes are lysed and eosinophils are easily seen, no critical time intervals must be adhered to, and these stains are easily made up. Counting chambers of large capacity (Fuchs-Rosenthal or Spiers) also simplify the procedure. With any technique, the blood cells should be counted within four hours of the time the blood is drawn.

SYMPTOMS FOLLOWING GASTRECTOMY

To the Editor:—*Ten years ago a 27-year-old man in excellent health complained of gradual loss of weight, fulness after meals, nausea, and some vomiting for several months. X-ray examination revealed a filling defect of the pylorus, no free acid even after administration of histamine, and gastroscopic signs of a few small superficial ulcerations. Because of x-ray evidence of malignancy, a subtotal gastrectomy, posterior polya type, was done. Examination of a section obtained at surgery showed grade three ulcerative gastritis. For the next six years there was a severe dumping syndrome with inability to eat eggs, cream, and very sweet mixtures. This was coupled with severe burning, which kept him up nightly and amazingly enough was occasionally relieved with aluminum hydroxide gel (Gelusil), even though he had no free acid. Vomiting of bile, which regurgitated nightly into the lower esophagus, gave relief. Normocytic hypochromic anemia developed but responded well to treatment with vitamin* B_{12} *and folic acid; he had an increase in weight and reduced upper gastric burning. X-ray examinations twice yearly have shown no abnormalities, with open stoma and fairly normal mucosa. Since he is disqualified for life insurance and it is feared that the histamine-fast achlorhydria may be a precursor of carcinoma, what information on prognosis can you give? There is no history of carcinoma in the family except for an 83-year-old father with stomach ulcers. How would you handle this case?*

M.D., Michigan.

Answer.—1. This patient will require further diagnostic work-up. Since he has a history of intolerance to "very sweet mixtures" and nocturnal burning and vomiting, there is a suggestion of vagotonic insular imbalance. An intravenous glucose tolerance test and a Hollander test would verify this. Incidentally, the Hollander test, if negative, would possibly rule out his presumed achlorhydria. Relief of symptoms with aluminum hydroxide gel (Gelusil) and his nocturnal burning suggest the presence of acid despite the fact that none has been found heretofore. His nocturnal vomitus should also be examined for acid because bile, in the presence of free acid, turns from yellow to green. If the vomitus is green, free acid is present. 2. It is the consensus among gastroenterologists that there is a fundamental relationship between chronic gastritis and carcinoma of the stomach, but no statistics are available at this time. A definite risk or age of occurrence of carcinoma in this patient cannot now be stated. 3. This man should have frequent (at least six daily) small feedings of a bland, convalescent ulcer diet. Since he apparently is sensitive to sugars, he should be allowed no free sugar. Since Gelusil has at times made him comfortable, he should take it regularly 45 minutes to 1 hour after meals and after his bedtime feeding. He should have a glass of milk and some crackers, as well as aluminum hydroxide gel, at his bedside to relieve his nocturnal burning, if it should continue. He should be given one of the anticholinergic drugs before meals and at bedtime. It is unusual that vitamin B_{12} and folic acid should improve a hypochromic anemia; however, 30 mg. of vitamin B_{12} should be given parenterally once every two to four weeks, depending on the patient's needs. This will be determined by careful serial hemograms. He should have repeated upper gastrointestinal x-ray series every three to six months and, if possible, yearly gastroscopy. His stool should be examined for occult blood frequently.

PREVENTION OF FUNGUS INFECTIONS OF FEET

To the Editor:—*Applicants for work in an industrial plant are examined in rooms where their bare feet are exposed to contact with a polished terrazzo floor. Fungus infection of the skin of the feet among these men is common. Does the above procedure spread this infection?*

M.D., California.

Answer.—According to present concepts, the danger of transmitting active or symptomatic attacks of fungus infections of the feet by walking over floors is minimal (*Arch. Derma & Syph.* 45:670 [April] 1942). Ordinary washing of the floor and routine cleanliness should be more than sufficient to take care of the problem of new infections from the floors. To reduce, as far as possible, any activation of latent infection or flare-ups, the men should wear properly fitting, well-ventilated footgear and use a standard mild dusting powder between the toes and in the socks. Routine measures for this form of prophylaxis, as well as other logical approaches, have been set forth in detail in an article entitled "Athlete's Foot" (*Hygeia* 19:522 [July] 1941 [reprinted in 1951]). Newer studies now in progress have all, thus far, supported the concept that the role of fungi in water, floors, clothing, and footgear is negligible in the production of attacks of dermatophytosis (athlete's foot). Quiescent infections flare up principally when moisture, humidity, friction, and other factors produce conditions that allow the fungi to multiply more rapidly and reduce the local resistance of the skin areas to their pathogenic action.

EDEMA OF UNKNOWN ORIGIN

To the Editor:—*In regard to the discussion of edema of unknown origin in Queries and Minor Notes, Aug. 1, 1953, I have observed three patients, all women, who had a certain type of edema while undergoing psychotherapy. The distribution of this edema was in the extremities, unilateral, and of varying intensity. Laboratory tests failed to show any deviant values. The usual diuretic regimen and use of antihistaminic preparations and thyroid extract were of no avail. Psychologically all three patients were suffering from neurotic depression with hysterical features. The swelling regularly followed a frustrating situation in which the patient's character make-up made expression of anger impossible. Instead these women became depressed. It appears that the edema is a form of weeping of the tissues similar to lachrymation or rhinorrhea. The ability of the patient to abreact his pent-up anger without any disturbance of the conscience is followed by the disappearance of the edema. In one patient an edema of the ankle vanished in about 45 minutes when under hypnosis she wept. For this reason I would suggest a careful search for neurotic depression in all patients with unexplained edema.*

BRAIN INJURIES

To the Editor:—*In Queries and Minor Notes of Sept. 26, 1953, the question about low diastolic blood pressure in certain types of brain injury is answered as follows: "A lowered diastolic pressure is not commonly seen in persons who have had an intracranial cerebral injury and is not to be correlated with such an injury." H. E. Mock in his book, "Skull Fractures and Brain Injuries" (Baltimore, Williams and Wilkins Company, 1950, p. 704) writes that in 1929 he described a group of patients who were referred to him because of mild, persistent, postcerebral injury symptoms. Few of this group had definite physical symptoms except bradycardia and a rather persistent low diastol blood pressure, often below 60 mm. Hg. The only ot positive finding was increased spinal fluid pressure. common factor in all their histories was a short and adequate treatment without direct or indirect spinal fl drainage. Since 1929 Dr. Mock has observed many simi cases. Low diastolic pressure is also of great importance in acute intracranial injuries. The treatment of the condition is bed rest, administration of hypertonic solutions for dehydration, and, when indicated, repeated lumbar punctures.*
